<p><i>Francesco Marcelloni</i></p>  <h2>To Pass Examination</h2> <ul style="list-style-type: none"> <li>• Project <ul style="list-style-type: none"> <li>• Pre-requisite to take the exam is the development of a Web application which performs some specific service. You can find all the relevant information at the following address: <a href="http://info.ipt.unipi.it/~france/p_docs/pweb/home.html">http://info.ipt.unipi.it/~france/p_docs/pweb/home.html</a></li> </ul> </li> <li>• Exam <ul style="list-style-type: none"> <li>• Practical exam performed in laboratory (approximately 1.5 hours)</li> </ul> </li> <li>• Final Mark and Project Evaluation <ul style="list-style-type: none"> <li>• Only if the exam is passed (mark &gt;=18), then the project will be discussed and a final mark will be assigned based on the marks obtained both in the exam and in the project</li> </ul> </li> </ul>	<p><i>Francesco Marcelloni</i></p> 	<p><i>Francesco Marcelloni</i></p>  <h2>World Wide Web</h2> <ul style="list-style-type: none"> <li>■ World Wide Web (WWW): network of information resources.</li> <li>■ Information resources: documents or pages which can contain link to other documents or pages with correlated information</li> <li>■ Documents with only text: Hypertext</li> <li>■ Documents with also images, voice and so on: Hypermedia</li> <li>■ Users access documents, independently of their location, through interactive programs, called browsers, or other multimedia programs.</li> <li>■ Such programs allow transferring these documents, showing the contents, navigating through the hypertext and hypermedia network.</li> </ul>

## Web documents

- A web document can consist of up to three layers
  - Content
  - Presentation
  - Behaviour

7

## Presentation Layer

- The *presentation layer* defines **how the content will appear** to a human being who accesses the document in one way or another.
- The conventional way to view a web page is with a regular web browser, of course, but that is only one of many possible access methods.
  - For example, content can also be converted to synthetic speech for users who have impaired vision or reading difficulties.

9

## Basic concept

- HTML -> structure and content
- CSS -> style and appearance
- Javascript -> behavior

Example: <h2>Via Diotisalvi 2</h2>

!!!

```
<h2>Address</h2>
<p>Via Diotisalvi 2</p>
```

<font size="3" color="red">This is some text!</font>

Use CSS to define the font face, font size, and font color of text.

11

## Content Layer

- The *content layer* is always present.
- It **comprises the information the author wishes to convey** to his or her audience, and is embedded within HTML markup that defines its structure and semantics.
- Most of the content on the Web today is text, but content can also be provided through images, animations, sound, video, and whatever else an author wants to publish.

8

## Behavior Layer

- The *behavior layer* involves **real-time user interaction** with the document.
- This task is normally handled by **JavaScript**.
- The interaction can be anything from a trivial **validation** that ensures a required field is filled in before an order form can be submitted, to **sophisticated web applications** that work much like ordinary desktop programs.

10

## WWW – Three basic mechanisms

- WWW relies on three basic mechanisms:
  - A **uniform naming scheme** for locating resources on the Web (e.g., URIs)
  - **Protocols**, for access to named resources over the Web (e.g., HTTP), followed by ":"//"
  - **Hypertext**, for easy navigation among the resources (e.g., HTML)

12

## Uniform Resource Identifier (URI)

- Each information resource on the Web has an address which can be codified by a **URI**.
- A URI is defined as
 
$$<\text{scheme}>:<\text{scheme-specific-part}>$$
- The **<scheme>** is the **name** of the mechanism used to access the resource (for instance, http protocol)
  - A colon character (:)
  - A **scheme-specific part**.

For instance

  - The **name of the machine** hosting the resource (for instance, [www.w3.org](http://www.w3.org))
  - The **name of the resource itself**, given as path

13

## Universal Resource Identifier (URI)

- A **Uniform Resource Name** (URN) is a URI that identifies a resource by name, in a particular **namespace**. The resource does not need to necessarily be network homed.
- For example, the URN [urn:isbn:0-393-36341-1](#) is a URI that specifies the identifier system, i.e. International Standard Book Number (**ISBN**), as well as the unique reference within that system and allows one to talk about a book, but does not suggest where and how to obtain an actual copy of it.
- URN - person's name
- URL – person's street address.

15

## Universal Resource Identifier (URI)

- In HTML, URIs are used to:
- **Link** to another document or resource,
  - **Link** to an external style sheet or script,
  - **Include** an image, object, or applet in a page,
  - **Create** an image map,
  - **Submit** a form,
  - **Create** an iframe document,
  - **Cite** an external reference,
  - **Refer** to metadata conventions describing a document

17

## Universal Resource Identifier (URI)

- A **URI** may be a locator (URL) or a name (URN), or both.
- A **Uniform Resource Locator** (URL) is a URI that, in addition to identifying a **resource**, specifies the means of acting upon and obtaining the representation.

For example, the URL <http://www.w3.org/TR>

14

## Universal Resource Identifier (URI)

### Fragment Identifier

Some URIs refer to a location within a resource. The URI ends with "#" followed by an anchor identifier (called the **fragment identifier**).

[http://somesite.com/html/top.html#section\\_2](http://somesite.com/html/top.html#section_2)

### Relative URI

A **relative URI** contains no naming scheme information. Relative URIs are resolved to full URIs using a base URI.

``

<http://somesite.com/icons/logo.gif>

16

## Protocols

- [http](#) - Hypertext transfer Protocol
- [ftp](#) - File Transfer protocol
- [mailto](#) - Electronic mail address
- [news](#) - USENET news
- [file](#) - Host-specific file names

18

## Protocol HTTP

- HTTP is a **request-response** standard typical of **client-server** computing: **web browsers** typically act as clients, while an application running on the computer hosting the **web site** acts as a server.
  - The client establishes a connection with the server and sends a request for a document
  - The server replies to the request by using the connection opened by the client
- Since the **protocol is stateless** (the server does not recognise the client and does not record the requests), if the connection falls, the request has to be repeated.

19

## HTML

- HTML 5
  - Compatibility
  - Utility
    - The user is king
  - Interoperability simplification
    - Native browser ability instead of complex JavaScript code
    - Powerful yet simple HTML5 APIs
    - HTML5 specification is also more detailed than previous ones to prevent misinterpretation: the specification is over 900 pages long!
    - HTML5 is also designed to handle errors well, with a variety of improved and ambitious error handling plans. It prefers graceful error recovery to hard failure, again giving top priority to the interest of the end user.
  - Universal Access
    - Accessibility: support users with disabilities
    - Media Independence
    - Support for all world languages

21

## HTML 5.0 Document Structure

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <meta charset="utf-8">
    <title> My first HTML document </title>
    <!-- A simple html document -->
  </head>
  <body>
    <p> Hello world! </p>
  </body>
</html>
```

23

## HTML Syntax

- HyperText Markup Language (HTML) is the language used to publish information on the Web
- HTML 4.01 is an Standard Generalized Markup Language (SGML) application conforming to International Standard ISO 8879.
  - Publish online documents with headings, text, tables, lists, photos, etc.
  - Retrieve online information via hypertext links, at the click of a button.
  - Design forms for conducting transactions with remote services.
  - Searching for information, making reservations, ordering products, etc.
  - Include spread-sheets, video clips, sound clips, and other applications directly in their documents.

20

## Constructs used in HTML

- Elements
  - Everything from the start tag to the end tag
 

```
<h1>Sample page</h1>
```
- Attributes
  - Provide additional information about HTML elements
 

```
<p>This is a <a href="demo.html">simple</a> sample.</p>
```
- Text
  - Text is allowed inside elements, attribute values and comments
- Character references
  - Examples: &acute; (é) &egrave; (è)
- Comments
  - Examples: <!-- comment -->

24

## HTML Elements

```
<start_tag attribute_list>
    element_content
<end_tag>
```

- The attribute list may contain the name and the identifier of the element
- The element names and identifiers are always case-insensitive.
- Some HTML elements have **empty content**. Empty elements are closed in the start
  - <br> is an empty element without a closing tag (it defines a line break).
- Most HTML elements can have **attributes**
- Most HTML elements can be **nested**.

25

## HTML Elements

- **HTML tags are not case sensitive:** <P> means the same as <p>.
- Plenty of web sites use uppercase HTML tags in their pages.
- The World Wide Web Consortium (W3C) recommends lowercase in HTML 4, and demands lowercase tags in future versions of (X)HTML

27

## Element definitions Category

### Categories

- Each element in HTML falls into zero or more categories that group elements with similar characteristics together.

#### Categories:

[Flow content](#)  
[Palpable content](#)

29

## HTML Elements

- Note: Most browsers will display HTML correctly even if you forget the end tag:

<p>This is a paragraph

- The example above will work in most browsers, but **don't rely on it**. Forgetting the end tag can produce unexpected results or errors.
- **Elements are not tags.** Some people refer to elements as tags (e.g., "the p tag"). For instance, the head element is always present, even though both start and end head tags may be missing in the markup.

26

## Element definitions An example

### 4.4.1 The p element

#### Categories:

[Flow content](#)  
[Palpable content](#)

#### Contexts in which this element can be used:

Where [flow content](#) is expected.

#### Content model:

[Phrasing content](#)

#### Content attributes:

[Global attributes](#)

#### Tag omission in text/html:

A `p` element's [end tag](#) may be omitted if the `p` element is immediately followed by an `address`, `article`, `aside`, `blockquote`, `div`, `dl`, `fieldset`, `footer`, `form`, `h1`, `h2`, `h3`, `h4`, `h5`, `h6`, `header`, `hr`, `main`, `nav`, `ol`, `p`, `pre`, `section`, `table`, or `ul` element, or if there is no more content in the parent element and the parent element is not an `a` element.

#### Allowed ARIA role attribute values:

[Any role value](#)

#### Allowed ARIA state and property attributes:

[Global aria-\\* attributes](#)

Any `aria-` attributes applicable to the allowed roles.

#### DOM interface:

`IDL` `interface HTMLParagraphElement : HTMLElement {};`

### Content Type

Content Type	Description
Embedded	Content that imports other resources into the document, for example <code>audio</code> , <code>video</code> , <code>canvas</code> , and <code>iframe</code>
Flow	Elements used in the body of documents and applications, for example <code>form</code> , <code>h1</code> , and <code>small</code>
Heading	Section headers, for example <code>h1</code> , <code>h2</code> , and <code>hgroup</code>
Interactive	Content that users interact with, for example <code>audio</code> or <code>video controls</code> , <code>button</code> , and <code>textarea</code>
Metadata	Elements—commonly found in the <code>head</code> section—that set up the presentation or behavior of the rest of the document, for example <code>script</code> , <code>style</code> , and <code>title</code>
Phrasing	Text and text markup elements, for example <code>mark</code> , <code>kbd</code> , <code>sub</code> , and <code>sup</code>
Sectioning	Elements that define sections in the document, for example <code>article</code> , <code>aside</code> , and <code>title</code>

30

<p><i>Università di Pisa</i></p> <h2>Element definitions</h2> <h3>Context</h3> <ul style="list-style-type: none"> <li>Context in which the element can be used           <ul style="list-style-type: none"> <li>A non-normative description of where the element can be used               <ul style="list-style-type: none"> <li>For simplicity, only the most specific expectations are listed. For example, an element that is both flow content and phrasing content can be used anywhere that either flow content or phrasing content is expected, but since anywhere that flow content is expected, phrasing content is also expected (since all phrasing content is flow content), only "where phrasing content is expected" will be listed.</li> </ul> </li> </ul> </li> </ul> <p><b>Contexts in which this element can be used:</b> Where <a href="#">flow content</a> is expected.</p>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Element definitions</h2> <h3>Content</h3> <ul style="list-style-type: none"> <li>Content model           <ul style="list-style-type: none"> <li>A normative description of what content must be included as children and descendants of the element.</li> </ul> </li> </ul> <p><b>Content model:</b> <a href="#">Phrasing content.</a></p>

<p><i>IN SUPERME DIGNITATI 1343</i></p> <p><i>Università di Pisa</i></p> <h2>Element definitions</h2> <h3>DOM Interface</h3> <ul style="list-style-type: none"> <li>DOM (Document Object Model) interface           <ul style="list-style-type: none"> <li>A normative definition of a DOM interface that such elements must implement.</li> </ul> </li> <li>What is DOM?           <ul style="list-style-type: none"> <li>Let us consider the following example</li> </ul> </li> </ul>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Element definitions</h2> <h3>DOM Interface</h3> <pre>&lt;!DOCTYPE html&gt; &lt;html&gt; &lt;head&gt; &lt;title&gt;Sample page&lt;/title&gt; &lt;/head&gt; &lt;body&gt; &lt;h1&gt;Sample page&lt;/h1&gt; &lt;p&gt;This is a &lt;a href="demo.html"&gt;simple&lt;/a&gt; sample.&lt;/p&gt; &lt;!-- this is a comment --&gt; &lt;/body&gt; &lt;/html&gt;</pre>

## Element definitions DOM Interface

- HTML user agents (e.g. Web browsers) parse this markup, turning it into a DOM (Document Object Model) tree.
- A DOM tree is an in-memory representation of a document.
- DOM trees contain several kinds of nodes, in particular a DocumentType node, Element nodes, Text nodes, Comment nodes, and in some cases ProcessingInstruction nodes.

**DOM interface:**

```
IDL interface HTMLParagraphElement : HTMLElement {};
```

37

## Element definitions

- WAI-ARIA (Web Accessibility Initiative -Accessible Rich Internet Applications specification)
- Client-side scripting causes accessibility problems when they do not convey the information necessary to Assistive Technologies (AT) – the devices and user systems typically used by people with disabilities. In simple terms assistive technology needs to know:
  1. **What things are:** The Role. (E.g., I am a checkbox)
  2. **What they are doing:** The state. (E.g., I am now checked)
  3. **What the relationships are.** (E.g., I am labeled by that text, I am part of this group, etc.)
  4. **Also the focus needs to be accessible from the keyboard and the interaction needs to be predictable.** (E.g., you can tab to this checkbox and press enter, then I am checked)

39

## Element definitions

### ■ ARIA State and Properties attributes

- Every HTML element may have ARIA state and property attributes specified. These attributes are defined by [ARIA] in Section 6.6, Definitions of States and Properties (all aria-\* attributes).
- ARIA State and Property attributes can be used on any element.

Allowed [ARIA role attribute](#) values:

Any role value.

Allowed [ARIA state and property attributes](#):

Global aria-\* attributes

Any aria-\* attributes applicable to the allowed roles.

41

## Element definitions DOM Interface

```
<!DOCTYPE html>
<html>
<head>
<title>Sample page</title>
</head>
<body>
<h1>Sample page</h1>
<p>This is a <a href="demo.html">simple</a>
sample.</p>
<!-- this is a comment -->
</body>
</html>
```

38

## Element definitions

### ■ ARIA role attributes

- The attribute describes the role(s) the current element plays in the context of the document.
  - This could allow a user to make informed decisions on which actions may be taken on an element and activate the selected action in a device independent way.
- The document “Using WAI-ARIA” is a practical guide for developers on how to add accessibility information to HTML elements, which defines a way to make Web content and Web applications more accessible to people with disabilities.
- This document demonstrates how to use WAI-ARIA, which especially helps with dynamic content and advanced user interface controls developed with Ajax, HTML, JavaScript, and related technologies

40

## Metadata Content

- Metadata content is content that sets up the presentation or behavior of the rest of the content, or that sets up the relationship of the document with other documents, or that conveys other “out of band” information.
  - base link meta noscript script style template title

42

<p><i>Università di Pisa</i></p> <h2>Flow Content</h2>  <ul style="list-style-type: none"> <li>■ Most elements that are used in the body of documents and applications are categorized as flow content.</li> <li>■ a abbr address area (if it is a descendant of a map element) article aside audio b bdi bdo blockquote br button canvas cite code data datalist del dfn div dl em embed fieldset figure footer form h1 h2 h3 h4 h5 h6 header hr i iframe img input ins kbd keygen label main map mark math meter nav noscript object ol output p pre progress q ruby s samp script section select small span strong sub sup svg table template textarea time u ul var video wbr</li> </ul>	<p><i>Università di Pisa</i></p> <h2>Sectioning Content</h2>  <ul style="list-style-type: none"> <li>■ Sectioning content is content that defines the scope of headings and footers</li> <li>■ article aside nav section</li> </ul>
<p><i>Università di Pisa</i></p> <h2>Heading Content</h2>  <ul style="list-style-type: none"> <li>■ Heading content defines the header of a section (whether explicitly marked up using sectioning content elements, or implied by the heading content itself)</li> <li>■ h1 h2 h3 h4 h5 h6</li> </ul>	<p><i>Università di Pisa</i></p> <h2>Phrasing Content</h2>  <ul style="list-style-type: none"> <li>■ Phrasing content is the text of the document, as well as elements that mark up that text at the intra-paragraph level. Runs of phrasing content form paragraphs</li> <li>■ a abbr area (if it is a descendant of a map element) audio b bdi bdo br button canvas cite code data datalist del dfn em embed i iframe img input ins kbd keygen label map mark math meter noscript object output progress q ruby s samp script select small span strong sub sup svg template textarea time u var video wbr text</li> <li>■ Text, in the context of content models, means either nothing, or Text nodes. Text is sometimes used as a content model on its own, but is also phrasing content, and can be inter-element whitespace (if the Text nodes are empty or contain just space characters).</li> </ul>
<p><i>Università di Pisa</i></p> <h2>Embedded Content</h2>  <ul style="list-style-type: none"> <li>■ Embedded content is content that imports another resource into the document, or content from another vocabulary that is inserted into the document.</li> <li>■ audio canvas embed iframe img math object svg video</li> </ul>	<p><i>Università di Pisa</i></p> <h2>Interactive Content</h2>  <ul style="list-style-type: none"> <li>■ Interactive content is content that is specifically intended for user interaction.</li> <li>■ a audio (if the controls attribute is present) button embed iframe img (if the usemap attribute is present) input (if the type attribute is not in the hidden state) keygen label object (if the usemap attribute is present) select textarea video (if the controls attribute is present)</li> </ul>

<p><i>Università di Pisa</i></p> <h2>Palpable Content</h2> <ul style="list-style-type: none"> <li>As a general rule, elements whose content model allows any flow content or phrasing content should have at least one node in its contents that is palpable content and that does not have the hidden attribute specified.</li> <li>a abbr address article aside audio (if the controls attribute is present) b bdi bdoblockquote button canvas cite code data dfn div dl (if the element's children include at least one name-value group) em embed fieldset figure footer form h1 h2 h3 h4 h5 h6 header i iframe img input (if the type attribute is not in the hidden state) ins kbd keygen label main map mark math meter nav object ol (if the element's children include at least one li element) output p pre progress q ruby s samp section select small span strong sub sup svg table textarea time u ul (if the element's children include at least one li element) var video text that is not inter-element whitespace</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p>49</p>	<p><i>Università di Pisa</i></p> <h2>Script-supporting Elements</h2> <ul style="list-style-type: none"> <li>Script-supporting elements are those that do not represent anything themselves (i.e. they are not rendered), but are used to support scripts, e.g. to provide functionality for the user.</li> <li>script template</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p>50</p>
<p><i>Università di Pisa</i></p> <h2>Transparent content models</h2> <ul style="list-style-type: none"> <li>Some elements are described as transparent. The content model of a transparent element is derived from the content model of its parent element: the elements required in the part of the content model that is "transparent" are the same elements as required in the part of the content model of the parent of the transparent element in which the transparent element finds itself.</li> <li>For instance, an ins element inside a ruby element cannot contain an rt element, because the part of the ruby element's content model that allows ins elements is the part that allows phrasing content, and the rt element is not phrasing content.</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p>51</p>	<p><i>Università di Pisa</i></p> <h2>HTML Attributes</h2> <ul style="list-style-type: none"> <li>Attribute/value pairs appear before the final "&gt;" of an element's start tag.</li> <li>Any number of (legal) attribute value pairs, separated by spaces, may appear in an element's start tag.</li> <li>Attributes may appear in any order.</li> <li>The attribute value can remain unquoted if it does not contain space characters or any of " ` = &lt; or &gt;. <p><i>Università di Pisa</i></p> <h2>Attributes</h2> <ul style="list-style-type: none"> <li>Example &lt;a href="http://www.w3schools.com"&gt;This is a link&lt;/a&gt; HTML links are defined with the &lt;a&gt; tag. The link address is provided as an attribute</li> <li>Attribute names are always case-insensitive.</li> <li>Attribute values are generally case-insensitive.</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p>53</p>	<p><i>Università di Pisa</i></p> <h2>Attributes</h2> <ul style="list-style-type: none"> <li>Attribute values may only contain: <ul style="list-style-type: none"> <li>letters (a-z and A-Z),</li> <li>digits (0-9),</li> <li>hyphens (ASCII decimal 45),</li> <li>periods (ASCII decimal 46),</li> <li>underscores (ASCII decimal 95),</li> <li>colons (ASCII decimal 58).</li> </ul> </li> <li>The W3C recommends lowercase attributes/attribute values</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p>54</p>

## Global Attributes

### ■ Global Attributes

May be specified on all the HTML elements

- core attributes
- event-handler attributes
- xml attributes

55

## Global Attributes

### ■ Core Attributes

- **hidden**: Specifies that an element is not yet, or is no longer, relevant
- **id**: Specifies a unique id for an element
- **lang**: Specifies the language of the element's content
- **spellcheck**: Specifies whether the element represents an element whose contents are subject to spell checking and grammar checking.
- **style**: Specifies an inline CSS style for an element
- **tabindex**: Specifies the tabbing order of an element
- **title**: Specifies extra information about an element
- **translate**: specifies whether the content of an element should be translated or not (not properly supported in any of the major browsers)

57

## Global Attributes

### ■ Event-handler Attributes (continued)

- **ondragend** - User ended dragging element.
- **ondragenter** - User's drag operation entered element.
- **ondragleave** - User's drag operation left element.
- **ondragover** - User is continuing drag operation over element.
- **ondragstart** - User started dragging element.
- **onerror** - element failed to load properly.
- **onfocus** - element received focus.
- **oninput** - user changed the value of element (form control).
- **oninvalid** - element (form control) did not meet validity constraints.
- **onkeydown** - user pressed down a key.

59

## Global Attributes

### ■ Core Attributes

- **accesskey**: specifies a shortcut key to activate/focus an element
- **class**: Specifies one or more classnames for an element (refers to a class in a style sheet)
- **contenteditable**: Specifies whether the content of an element is editable or not
- **dir**: Specifies the text direction for the content in an element
- **draggable**: Specifies whether an element is draggable or not
- **dropzone**: Specifies whether the dragged data is copied, moved, or linked, when dropped (not implemented in the browsers)

56

## Global Attributes

### ■ Event-handler Attributes

An event handler content attribute is a content attribute for a specific event handler. The name of the content attribute is the same as the name of the event handler.

Some common events attributes are

- **onabort** - Load of element was aborted by the user.
- **onblur** - Element lost focus.
- **onchange** - User committed a change to the value of element (form control).
- **onclick** - User pressed pointer button down and released pointer button over element
- **ondblclick** - User clicked pointer button twice over element
- **ondrag** - User is continuing to drag element.

58

## Global Attributes

### ■ Event-handler Attributes (continued)

- **onkeypress** - User pressed down a key that is associated with a character value.
- **onkeyup** - User released a key.
- **onLoad** - Element finished loading.
- **onmousedown** - User pressed down pointer button over element.
- **onmousemove** - User moved mouse.
- **onmouseout** - User moved pointer off boundaries of element.
- **onmouseover** - User moved pointer into boundaries of element or one of its descendant elements.
- **onmouseup** - User released pointer button over element.

60

<p><i>Università di Pisa</i></p> <h2>Global Attributes</h2> <ul style="list-style-type: none"> <li>■ <b>Event-handler Attributes (continued)</b> <ul style="list-style-type: none"> <li>▪ <b>onmousewheel</b> - User rotated wheel of mouse or other device in a manner that emulates such an action.</li> <li>▪ <b>onreset</b> - the form element was reset.</li> <li>▪ <b>onscroll</b> - Element or document view was scrolled.</li> <li>▪ <b>onselect</b> – User selected some text.</li> <li>▪ <b>onsubmit</b> – The form element was submitted.</li> </ul> </li> <li>■ Other event-handler attributes can be found in the HTML5 specification.</li> </ul>	<p><i>Francesco Marcelleni</i></p>	<p><i>Università di Pisa</i></p> <h2>Character references</h2> <ul style="list-style-type: none"> <li>■ <i>Character references</i> are a form of markup for representing single individual characters. 		<p>66</p>

## Authoring HTML documents

- Separate structure and presentation
  - reduces the cost of serving a wide range of platforms, media, etc., and facilitates document revisions.
- Consider universal accessibility to the Web
  - authors should consider how their documents may be rendered on a variety of platforms
  - in order for documents to be interpreted correctly, authors should include in their documents information about the natural language and direction of the text, how the document is encoded, and other issues related to internationalization.
- Help browsers with incremental rendering
  - Allows browsers to render documents more quickly. For instance, to design tables for incremental rendering

67

## The Elements of HTML

68

## HTML 5.0 Document Structure

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <meta charset="utf-8">
    <title> My first HTML document </title>
  </head>
  <body>
    <p> Hello world! </p>
  </body>
</html>
```

69

## Root element HTML Element

- Cache Manifest basic:
  - HTML5 introduces application cache, which means that a web application is cached, and accessible without an internet connection.
 

```
<html manifest="demo.appcache">
```
  - The manifest file is a simple text file, which tells the browser what to cache (and what to never cache). The manifest file has three sections:
    - **CACHE MANIFEST** - Files listed under this header will be cached after they are downloaded for the first time
    - **NETWORK** - Files listed under this header require a connection to the server, and will never be cached
    - **FALLBACK** - Files listed under this header specifies fallback pages if a page is inaccessible

71

## Root element HTML Element

### ■ Example of manifest file

```
CACHE MANIFEST
# 2012-02-21 v1.0.0
/theme.css
/logo.gif
/main.js
```

NETWORK:  
login.asp

FALLBACK:  
/html/ /offline.html

72

## Document Metadata Head Element

- The **head element** contains information about the current document, such as its **title**, **keywords** that may be useful to search engines, and other data that is not considered document content.
- Every HTML document **must** have a **title element** in the head section.

```
<head>
<title>HTML course</title>
</head>
```

73

## Document Metadata Meta Data

- Meta Data** -- information about a document
- ```
<head>
<meta charset="utf-8">
<meta name="author" content="Hege Refsnes">
<meta name="description" content="Free Web tutorials">
<meta name="generator" content="Notepad++">
<meta name="keywords" content="HTML,CSS,XML,JavaScript">
<title>HTML5 Example</title>
</head>
```
- Possible values for name: **application-name**, **author**, **description**, **generator**, **keywords**

75

## Document Metadata Meta Data

- When **several meta elements** provide language-dependent information, search engines may filter on the **lang** attribute to display search results using the language preferences of the user.

```
<!-- For speakers of US English -->
<meta name="keywords" lang="en-us"
content="vacation, Greece, sunshine">
<!-- For speakers of British English -->
<meta name="keywords" lang="en"
content="holiday, Greece, sunshine">
<!-- For speakers of French -->
<meta name="keywords" lang="fr"
content="vacances, Gr&egrave;ce, soleil">
```

77

## Document Metadata Title

- Use the **title element** to identify the **contents of a document**.
- Since users often consult documents out of context, authors **should provide context-rich titles**. Thus, instead of a title such as "A study", authors should supply a title such as "A study of population dynamics" instead.
- User agents must always make the content of the title element available to users
- Titles may contain character entities (for accented characters, special characters, etc.), but **may not contain other markup** (including comments).

74

## Document Metadata Meta Data

- The **http-equiv attribute** integrates an HTTP header with the information in the content attribute.
- The value of the http-equiv attribute depends on the value of the content attribute.

```
<meta http-equiv="Refresh" content="10">
```

Defines a time interval for the document to refresh itself

76

## Document Metadata Base element

- The **base element** allows authors to **specify the document base URL for the purposes of resolving relative URLs**, and the name of the default browsing context for the purposes of following hyperlinks. The element does not represent any content beyond this information.

```
<!DOCTYPE html>
<html> <head>
<meta charset="utf-8">
<title>This is an example for the &lt;base&gt; element</title>
<base href="http://www.example.com/news/index.html">
</head>
<body>
<p>Visit the <a href="archives.html">archives</a>.</p>
</body>
</html>
```

The link in the above example would be a link to  
["http://www.example.com/news/archives.html".](http://www.example.com/news/archives.html)

78

## Sections Document Organization

### Header Element

- The header element represents introductory content for its nearest ancestor sectioning content or sectioning root element. A header typically contains a group of introductory or navigational aids.
- When the nearest ancestor sectioning content or sectioning root element is the body element, then it applies to the whole page.
- The header element is not sectioning content; it doesn't introduce a new section.

```
<header>
  <!-- header content goes in here -->
</header>
```

85

## Sections Document Organization

### Nav Element

- The nav element represents a section of a page that links to other pages or to parts within the page: a section with navigation links.
- When the nearest ancestor sectioning content or sectioning root element is the body element, then it applies to the whole page.
- The header element is not sectioning content; it doesn't introduce a new section.

```
<nav>
  <!-- navigation menu goes in here -->
</nav>
```

86

## Sections Document Organization

### Section Element

- The section element represents a generic section of a document or application.
- A section, in this context, is a thematic grouping of content. The theme of each section should be identified, typically by including a heading (h1-h6 element) as a child of the section element.
- Examples of sections would be chapters, the various tabbed pages in a tabbed dialog box, or the numbered sections of a thesis.

```
<section id="sidebar1">
  <!-- sidebar content goes in here -->
</section>
```

87

## Sections Document Organization

### Aside Element

- The aside element represents a section of a page that consists of content that is tangentially related to the content around the aside element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography.
- The element can be used for typographical effects like pull quotes or sidebars, for advertising, for groups of nav elements, and for other content that is considered separate from the main content of the page.

```
<aside>
  <!-- article content goes in here -->
</aside>
```

89

## Sections Document Organization

### Footer Element

- Represents a footer for its nearest ancestor sectioning content or sectioning root element.
  - contains information about its section such as who wrote it, links to related documents, copyright data, and the like.
- When the footer element contains entire sections, they represent appendices, indexes, long colophons, verbose license agreements, and other such content.
  - Contact information for the author or editor of a section belongs in an address element, possibly itself inside a footer.

```
<footer>
  <!-- article content goes in here -->
</footer>
```

90

<p><i>Università di Pisa</i></p> <h2 style="color: red;">Sections Document Organization</h2>	<p><i>Francesco Marcelleni</i></p> <h2 style="color: red;">Sections Document Organization</h2>	<p><i>Francesco Marcelleni</i></p>
<p><b>Heading Elements</b></p> <ul style="list-style-type: none"> <li>■ A heading element briefly describes the topic of the section it introduces. Heading information may be used by user agents, for example, to construct a table of contents for a document automatically.</li> <li>■ There are <b>six levels</b> of headings in HTML with h1 as the most important and h6 as the least.</li> <li>■ Use HTML headings for headings only. <b>Don't use headings to make text BIG or bold.</b></li> <li>■ Search engines use your headings to index the structure and content of your web pages. Since users may skim your pages by its headings, it is important to use headings to show the document structure.</li> <li>■ h1 headings should be used as main headings, followed by h2 headings, then less important h3 headings, and so on.</li> </ul>	<p><b>Address Element</b></p> <ul style="list-style-type: none"> <li>■ The address element represents the contact information for its nearest <b>article or body element ancestor</b>. If that is the body element, then the contact information applies to the document as a whole.</li> <li>■ The <b>address element must not be used to represent arbitrary addresses</b> (e.g. postal addresses), unless those addresses are in fact the relevant contact information.</li> <li>■ Typically, the address element would be included along with other information in a footer element.</li> </ul> <pre>&lt;address&gt;   For more details, contact   &lt;a href="mailto:js@example.com"&gt;John Smith&lt;/a&gt; &lt;/address&gt;</pre>	<p><i>Francesco Marcelleni</i></p>

<p><i>Francesco Marcelleni</i></p> <h2>Grouping Content Element pre</h2> <ul style="list-style-type: none"> <li>The <b>pre</b> element represents a block of preformatted text, in which structure is represented by typographic conventions rather than by elements.</li> <li>Some examples of cases where the <b>pre</b> element could be used: <ul style="list-style-type: none"> <li>Including an e-mail, with paragraphs indicated by blank lines, lists indicated by lines prefixed with a bullet, and so on.</li> <li>Including fragments of computer code, with structure indicated according to the conventions of that language.</li> <li>Displaying ASCII art.</li> </ul> </li> </ul> <pre>&lt;p&gt;This is the &lt;code&gt;Panel&lt;/code&gt; constructor:&lt;/p&gt; &lt;pre&gt;&lt;code&gt;function Panel(element, canClose, closeHandler) { this.element = element; this.canClose = canClose; this.closeHandler = function () { if (closeHandler) closeHandler(); }&lt;/code&gt;&lt;/pre&gt;</pre> <p style="text-align: center;">101</p>	<p><i>Francesco Marcelleni</i></p> <h2>Grouping Content Element blockquote</h2> <ul style="list-style-type: none"> <li>The <b>blockquote</b> element represents content that is quoted from another source, optionally with a citation which must be within a footer or <b>cite</b> element, and optionally with in-line changes such as annotations and abbreviations.</li> </ul> <pre>&lt;blockquote&gt; The people recognize themselves in their commodities; they find their soul in their automobile, hi-fi set, split-level home, kitchen equipment. — &lt;cite&gt;&lt;a href="http://en.wikipedia.org/wiki/Herbert_Marcuse"&gt;Herbert Marcuse&lt;/a&gt;&lt;/cite&gt; &lt;/blockquote&gt;</pre> <p style="text-align: center;">102</p>

## Grouping Content Element figure

- The **figure** element represents some flow content, optionally with a caption, that is self-contained (like a complete sentence) and is typically referenced as a single unit from the main flow of the document.
- The element can thus be used to annotate illustrations, diagrams, photos, code listings, etc.
- The first **figcaption** element child of the element, if any, represents the **caption of the figure element's contents**. If there is no child figcaption element, then there is no caption.
- A figure element's contents are part of the surrounding flow. If the purpose of the page is to display the figure, for example a photograph on an image sharing site, the figure and figcaption elements can be used to explicitly provide a caption for that figure.

103

## Grouping Content Element figure

Some uses

```
<figure>
<p>'Twas brillig, and the slithy toves<br>
Did gyre and gimble in the wabe;<br>
All mimsy were the borogoves,<br>
And the mome raths outgrabe.</p>
<figcaption><cite>Jabberwocky</cite> (first verse). Lewis Carroll, 1832-98</figcaption>
</figure>
```

```
<figure>
<figcaption>Oil-based paint on canvas. Maria Towle, 1858.</figcaption>

</figure>
```

104

## Grouping Content Element div

- The **div** element has no special meaning at all. It represents its children. It can be used with the **class**, **lang**, and **title** attributes to mark up semantics common to a group of consecutive elements.
- Example: div used to set the language of two paragraphs at once

```
<div lang="en-GB">
<p>My other cat, coloured black and white, is a sweetie. He followed us to the pool today, walking down the pavement with us. Yesterday he apparently visited our neighbours. I wonder if he recognises that their flat is a mirror image of ours.</p>
<p>Hm, I just noticed that in the last paragraph I used British English. But I'm supposed to write in American English. So I shouldn't say "pavement" or "flat" or "colour"...</p>
</div>
```

105

## Grouping Content Unordered Lists

- HTML supports **ordered**, **unordered** and **definition** lists.
- Unordered lists**
  - An unordered list starts with the **<ul>** tag.
  - Each list item starts with the **<li>** tag.
  - The list items are marked with bullets (typically small black circles).

```
<p>I have lived in the following countries:</p>
<ul>
<li>Norway
<li>Switzerland
<li>United Kingdom
<li>United States
</ul>
```

107

## Grouping Content Ordered Lists

### Ordered lists

- An ordered list starts with the **<ol>** tag.
- Each list item starts with the **<li>** tag.
- The list items are marked with numbers.

The **li** element has an ordinal value.

The **value** attribute, if present, must be a **valid integer giving the ordinal value of the list item**. If the attribute's value cannot be converted to a number, the attribute must be treated as if it was absent. The attribute has no default value.

108

## Grouping Content Ordered Lists

### ■ Ordered lists

- The ol element has three specific attributes
  - **reversed** – number the list backwards
  - **start** – ordinal value of the first item
  - **type** – kind of list marker

The type attribute represents the state given in the cell in the second column of the row whose first cell matches the attribute's value; if none of the cells match, or if the attribute is omitted, then the attribute represents the decimal state

Keywords	State	Description
1 (U+0031)	decimal	Decimal numbers
a (U+0061)	lower-alpha	Lowercase latin alphabet
A (U+0041)	upper-alpha	uppercase latin alphabet
i (U+0069)	lower-roman	lowercase roman numerals
I (U+0049)	upper-roman	uppercase roman numerals

109

## Grouping Content Ordered Lists

### ■ Ordered lists (example 1)

```
<figure> <figcaption>The top 10 movies of all time</figcaption>
<ol reversed type="a">
<li value="10"><cite>Josie and the Pussycats</cite>, 2001</li>
<li value="9"><cite lang="sh">Црна мачка, бели мачор</cite>, 1998</li>
<li value="8"><cite>A Bug's Life</cite>, 1998</li>
<li value="7"><cite>Toy Story</cite>, 1995</li>
<li value="6"><cite>Monsters, Inc</cite>, 2001</li>
<li value="5"><cite>Cars</cite>, 2006</li>
<li value="4"><cite>Toy Story 2</cite>, 1999</li>
<li value="3"><cite>Finding Nemo</cite>, 2003</li>
<li value="2"><cite>The Incredibles</cite>, 2004</li>
<li value="1"><cite>Ratatouille</cite>, 2007</li>
</ol> </figure>
```

110

## Grouping Content Ordered Lists

### ■ Ordered lists (example 2)

```
<figure> <figcaption>The top 10 movies of all time</figcaption>
<ol reversed type="a">
<li><cite>Josie and the Pussycats</cite>, 2001</li>
<li><cite lang="sh">Црна мачка, бели мачор</cite>, 1998</li>
<li><cite>A Bug's Life</cite>, 1998</li>
<li><cite>Toy Story</cite>, 1995</li>
<li><cite>Monsters, Inc</cite>, 2001</li>
<li><cite>Cars</cite>, 2006</li>
<li><cite>Toy Story 2</cite>, 1999</li>
<li><cite>Finding Nemo</cite>, 2003</li>
<li><cite>The Incredibles</cite>, 2004</li>
<li><cite>Ratatouille</cite>, 2007</li>
</ol></figure>
```

111

## Grouping Content Ordered Lists

### ■ Ordered lists (example 2)

```
<figure> <figcaption>The top 10 movies of all time</figcaption>
<ol reversed type="a" start="10">
<li><cite>Josie and the Pussycats</cite>, 2001</li>
<li><cite lang="sh">Црна мачка, бели мачор</cite>, 1998</li>
<li><cite>A Bug's Life</cite>, 1998</li>
<li><cite>Toy Story</cite>, 1995</li>
<li><cite>Monsters, Inc</cite>, 2001</li>
<li><cite>Cars</cite>, 2006</li>
<li><cite>Toy Story 2</cite>, 1999</li>
<li><cite>Finding Nemo</cite>, 2003</li>
<li><cite>The Incredibles</cite>, 2004</li>
<li><cite>Ratatouille</cite>, 2007</li>
</ol></figure>
```

112

## Grouping Content Definition Lists

### ■ Definition lists

- Lists of items (terms), with a description of each item (term).
- A definition list starts with a **<dl>** tag (definition list).
- Each term starts with a **<dt>** tag (definition term).
- Each description starts with a **<dd>** tag (definition description).

Name-value groups may be terms and definitions, metadata topics and values, questions and answers, or any other groups of name-value data.

The values within a group are alternatives; multiple paragraphs forming part of the same value must all be given within the same dd element.

113

## Grouping Content Definition Lists

### ■ Definition lists (Example)

```
<dl>
<dt lang="en-US"> <dfn>color</dfn> </dt>
<dt lang="en-GB"> <dfn>colour</dfn> </dt>
<dd> A sensation which (in humans) derives from the ability of the fine structure of the eye to distinguish three differently filtered analyses of a view. </dd>
</dl>
```

114

# Text-level semantics

115

## Text-level semantics (Target)

Keyword	Ordinary effect	Effect in an <code>iframe</code> with...	
		<code>sandbox=""</code>	<code>sandbox="allow-top-navigation"</code>
none specified, for links and form submissions	current	current	current
empty string	current	current	current
<code>_blank</code>	new	maybe new	maybe new
<code>_self</code>	current	current	current
<code>_parent</code> if there isn't a parent	current	current	current
<code>_parent</code> if parent is also top	parent/top	none	parent/top
<code>_parent</code> if there is one and it's not top	parent	none	none
<code>_top</code> if top is current	current	current	current
<code>_top</code> if top is not current	top	none	top
name that doesn't exist	new	maybe new	maybe new
name that exists and is a descendant	specified descendant	specified descendant	specified descendant
name that exists and is current	current	current	current
name that exists and is an ancestor that is top	specified ancestor	none	specified ancestor/top
name that exists and is an ancestor that is not top	specified ancestor	none	none
other name that exists with common top	specified	none	none
name that exists with different top, if <code>familiar</code> and <code>one permitted sandboxed navigator</code>	specified	specified	specified
name that exists with different top, if <code>familiar</code> but not <code>one permitted sandboxed navigator</code>	specified	none	none
name that exists with different top, not <code>familiar</code>	new	maybe new	maybe new

117

## Text-level semantics Element a

- Example

```
<nav>
<ul>
  <li> <a href="http://www.unipi.it" target="_blank">New</a> </li>
  <li> <a href="http://www.unipi.it" target="_self">Self</a> </li>
  <li> <a href="http://www.unipi.it" target="top" rel="tag">Top</a> </li>
</ul>
</nav>
```

119

## Text-level semantics

### Element a

- If the `a` element has an `href` attribute, then it represents a hyperlink (a hypertext anchor) labeled by its contents.
- If the `a` element has no `href` attribute, then the element represents a placeholder for where a link might otherwise have been placed, if it had been relevant, consisting of just the element's contents.
- Attributes
  - `href` - Address of the hyperlink
  - `target` - Default browsing context for hyperlink navigation and form submission
  - `download` - Whether to download the resource instead of navigating to it, and its file name if so
  - `rel` - Relationship between the document containing the hyperlink and the destination resource
  - `hreflang` - Language of the linked resource
  - `type` - Hint for the type of the referenced resource

116

## Text-level semantics

### Element a

Brief description

Link type	Effect on...		Brief description
	link	and area	
<code>alternate</code>	Hyperlink	Hyperlink	Gives alternate representations of the current document.
<code>author</code>	Hyperlink	Hyperlink	Gives a link to the author of the current document or article.
<code>bookmark</code>	not allowed	Hyperlink	Gives the permalink for the nearest ancestor section.
<code>help</code>	Hyperlink	Hyperlink	Provides a link to context-sensitive help.
<code>icon</code>	External Resource	not allowed	Imports an icon to represent the current document.
<code>license</code>	Hyperlink	Hyperlink	Indicates that the main content of the current document is covered by the copyright license described by the referenced document.
<code>next</code>	Hyperlink	Hyperlink	Indicates that the current document is a part of a series, and that the next document in the series is the referenced document.
<code>nofollow</code>	not allowed	Annotation	Indicates that the current document's original author or publisher does not endorse the referenced document.
<code>noreferrer</code>	not allowed	Annotation	Requires that the user agent not send an HTTP <code>Referer</code> (sic) header if the user follows the hyperlink.
<code>prefetch</code>	External Resource	External Resource	Specifies that the target resource should be preemptively cached.
<code>prev</code>	Hyperlink	Hyperlink	Indicates that the current document is a part of a series, and that the previous document in the series is the referenced document.
<code>search</code>	Hyperlink	Hyperlink	Gives a link to a resource that can be used to search through the current document and its related pages.
<code>stylesheet</code>	External Resource	not allowed	Imports a stylesheet.
<code>tag</code>	not allowed	Hyperlink	Gives a tag (identified by the given address) that applies to the current document.

## Text-level semantics

### Elements em, strong, small

- The `em` element represents stress emphasis of its contents.
- The `strong` element represents strong importance, seriousness, or urgency (contents that the user needs to see sooner than other parts of the document) for its contents.
- The `small` element represents side comments such as small print.

#### Example

`<p>Example Corp today announced <em>record profits</em> for the second quarter <small>(Full Disclosure: Foo News is a subsidiary of Example Corp)</small>, <strong>leading to speculation about a third quarter merger with Demo Group</strong>.</p>`

<p><i>Università di Pisa</i></p> <h2>Text-level semantics Elements s and cite</h2> <ul style="list-style-type: none"> <li>The <b>s</b> element represents contents that are no longer accurate or no longer relevant.</li> </ul> <pre>&lt;p&gt;Buy our Iced Tea and Lemonade!&lt;/p&gt; &lt;p&gt;&lt;s&gt;Recommended retail price: \$3.99 per bottle&lt;/s&gt;&lt;/p&gt; &lt;p&gt;&lt;strong&gt;Now selling for just \$2.99 a bottle&lt;/strong&gt;&lt;/p&gt;</pre> <ul style="list-style-type: none"> <li>The <b>cite</b> element represents a reference to a creative work. It must include the title of the work or the name of the author(person, people or organization) or an URL reference, which may be in an abbreviated form as per the conventions used for the addition of citation metadata.</li> </ul> <pre>&lt;p&gt;In the words of &lt;cite&gt;Charles Bukowski&lt;/cite&gt; -</pre>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Text-level semantics Element q</h2> <ul style="list-style-type: none"> <li>The <b>q</b> element represents some phrasing content quoted from another source.</li> </ul> <pre>&lt;p&gt;The W3C page &lt;cite&gt;About W3C&lt;/cite&gt; says the W3C's mission is &lt;q cite="http://www.w3.org/Consortium/"&gt;To lead the World Wide Web to its full potential by developing protocols and guidelines that ensure long-term growth for the Web&lt;/q&gt;. I disagree with this mission.&lt;/p&gt;</pre>
<p><i>IN SUPERME DIGNITATI 1343</i></p> <p><i>Università di Pisa</i></p> <h2>Text-level semantics Elements dfn and abbr</h2> <ul style="list-style-type: none"> <li>The <b>dfn</b> element represents the defining instance of a term. The paragraph, description list group, or section that is the nearest ancestor of the dfn element must also contain the definition(s) for the term given by the dfn element.</li> <li>If the dfn element has a <i>title</i> attribute, then the exact value of that attribute is the term being defined.</li> <li>The <b>abbr</b> element represents an abbreviation or acronym, optionally with its expansion. The <i>title</i> attribute may be used to provide an expansion of the abbreviation. The attribute, if specified, must contain an expansion of the abbreviation, and nothing else.</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Text-level semantics Elements dfn and abbr</h2> <ul style="list-style-type: none"> <li>Example</li> </ul> <pre>&lt;p&gt;The &lt;dfn id=gdo&gt;&lt;abbr title="Garage Door Opener"&gt;GDO&lt;/abbr&gt;&lt;/dfn&gt; is a device that allows off-world teams to open the iris.&lt;/p&gt; &lt;!-- ... later in the document: --&gt; &lt;p&gt;Teal'c activated his &lt;a href="#gdo"&gt;&lt;abbr title="Garage Door Opener"&gt;GDO&lt;/abbr&gt;&lt;/a&gt; and so Hammond ordered the iris to be opened.&lt;/p&gt;</pre>
<p><i>IN SUPERME DIGNITATI 1343</i></p> <p><i>Università di Pisa</i></p> <h2>Text-level semantics Elem code, var, samp, kbd, sup, sub</h2> <ul style="list-style-type: none"> <li>The <b>code</b> element represents a fragment of computer code.</li> <li>The <b>var</b> element represents a variable.</li> <li>The <b>samp</b> element represents (sample) output from a program or computing system.</li> <li>The <b>kbd</b> element represents user input (typically keyboard input, although it may also be used to represent other input, such as voice commands).</li> <li>The <b>sup</b> element represents a superscript and the <b>sub</b> element represents a subscript.</li> </ul> <pre>&lt;p&gt;The coordinate of the &lt;var&gt;i&lt;/var&gt;th point is &lt;code&gt;(&lt;var&gt;x&lt;sub&gt;i&lt;/sub&gt;&lt;var&gt;i&lt;/var&gt;&lt;/sub&gt;&lt;/var&gt;,&lt;var&gt;y&lt;sub&gt;i&lt;/sub&gt;&lt;var&gt;i&lt;/var&gt;&lt;/sub&gt;&lt;/var&gt;)&lt;/code&gt;. For example, the 10th point has coordinate &lt;code&gt;(&lt;var&gt;x&lt;sub&gt;10&lt;/sub&gt;&lt;var&gt;10&lt;/var&gt;&lt;/code&gt;.&lt;/p&gt;</pre>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Text-level semantics Elements i, b and mark</h2> <ul style="list-style-type: none"> <li>The <b>i</b> element represents a <b>span</b> of text in an <b>alternate voice</b> or <b>mood</b>, or otherwise offset from the normal prose in a manner indicating a different quality of text, such as a taxonomic designation, a technical term, an idiomatic phrase from another language, transliteration, a thought, or a ship name in Western texts.</li> <li>The <b>b</b> element represents a <b>span</b> of text to which attention is being drawn for utilitarian purposes without conveying any extra <b>importance</b> and with no implication of an alternate voice or mood, such as key words in a document abstract, product names in a review, actionable words in interactive text-driven software, or an article lede.</li> <li>The <b>mark</b> element represents a <b>run</b> of text in one document <b>marked</b> or <b>highlighted</b> for <b>reference purposes</b>, due to its relevance in another context.</li> </ul>

## Text-level semantics

### Elements ruby, rt, rp

- The **ruby** element allows one or more spans of phrasing content to be marked with ruby annotations. Ruby annotations are short runs of text presented alongside base text, primarily used in East Asian typography as a guide for pronunciation or to include other annotations.
- The **rt** element marks the ruby text component of a ruby annotation.
- The **rp** element is used to provide fallback text to be shown by user agents that don't support ruby annotations.

```
<body>
  <ruby> ♥ <rp>: </rp><rt>Heart</rt><rp>.</rp></ruby>
  <ruby> ✩ <rp>: </rp><rt>Shamrock</rt><rp>.</rp></ruby>
  <ruby> * <rp>: </rp><rt>Star</rt><rp>.</rp></ruby>
</body>
```

127

## Text-level semantics

### Elements span, br, wbr

- The **span** element doesn't mean anything on its own, but can be useful when used together with the global attributes, e.g. class, lang, or dir. It **represents its children**.
- The **br** element represents a line break.
- The **wbr** element represents a line break opportunity.

`<p>So then he pointed at the tiger and screamed  
"there<wbr>is<wbr>no<wbr>way<wbr>you<wbr>are<wbr>ever  
<wbr>going<wbr>to<wbr>catch<wbr>me!"</p>`

129

## Edits

### Elements ins, del

- The **ins** element represents an addition to the document.
- The **del** element represents a removal from the document.
  - The **cite** attribute may be used to specify the address of a document that explains the change.
  - The **datetime** attribute may be used to specify the time and date of the change.

```
<h1>List of <del>fruits</del><ins>colors</ins></h1>
<ul>
<li><del datetime="2009-10-10T23:38-07:00">Apple</del></li>
<li>Orange</li>
<li><del>Pear</del></li>
<li><ins>Teal</ins></li>
<li><del>Lemon</del><ins>Yellow</ins></li>
<li><ins>Olive</ins></li>
</ul>
```

131

## Text-level semantics

### Elements bdi, bdo

- The **bdi** element represents a span of text that is to be isolated from its surroundings for the purposes of bidirectional text formatting.
- The **bdo** element represents explicit text directionality formatting control for its children.

```
<ul>
  <li>User <bdi>jcranmer</bdi>: 12 posts.
  <li>User <bdi>hober</bdi>: 5 posts.
  <li>User <bdi>نے!</bdi>: 3 posts.
</ul>
```

## Edits

130

## Embedded content

132

## Embedded Content

### The img element

- An **img** element represents an image.
- The **<img>** element is empty, which means that it contains attributes only and it has no closing tag.
- To display an image on a page, you need to use the **src** attribute. The value of the **src** attribute is the URL of the image you want to display on your page.
- The syntax of defining an image:  
``
- The browser puts the image where the image tag occurs in the document.
- Except where otherwise specified, the alt attribute must be specified and its value must not be empty; the value must be an appropriate functional replacement for the image.

133

## Embedded Content

### The img element

```
<p> <img src= "tower.jpg" width="40" height="40" alt="Tower of Pisa"> </p>
<p> <img src= "tower.jpg" width="90" height="90" alt="Tower of Pisa"> </p>
<p>
    You can make an image smaller or larger by changing the
    values of the "height" and "width" attributes.
</p>
```

134

## Embedded Content

### The img element

- An **img** is always in one of the following states:
  - Unavailable**
    - The user agent has not obtained any image data.
  - Partially available**
    - The user agent has obtained some of the image data.
  - Completely available**
    - The user agent has obtained all of the image data and at least the image dimensions are available.
  - Broken**
    - The user agent has obtained all of the image data that it can, but it cannot even decode the image enough to get the image dimensions (e.g. the image is corrupted, or the format is not supported, or no data could be obtained).

135

## Embedded Content

### The image map

- Image maps** allow authors to specify regions of an image and assign a specific action to each region (e.g., retrieve a document, run a program, etc.). When the region is activated by the user, the action is executed.
- An image map is created by associating an image with a specification of sensitive geometric areas on the image.
- The **map** element, in conjunction with an **img** element and any **area** element descendants, defines an image map. The element represents its children.
- The **name** attribute gives the map a name so that it can be referenced. The attribute must be present and must have a non-empty value with no space characters.

## Embedded Content

### The image map

<p>Click on the sun or on one of the planets to get more information:</p>

```
<div>

<map name="planetmap">
    <area shape="rect" coords="0,0,82,126" alt="Sun"
href="sun.html">
    <area shape="circle" coords="90,58,3" alt="Mercury"
href="mercur.html">
    <area shape="circle" coords="124,58,8" alt="Venus"
href="venus.html">
</map>
</div>
```

137

## Embedded Content

### The image map

- The **<area>** tag defines an area inside an image-map (an image-map is an image with clickable areas).
- The **area element is always nested** inside a **<map>** tag
- Note: The **usemap** attribute in the **<img>** tag is associated with the **map** element's **name** attribute, and creates a relationship between the image and the map.

## Embedded Content

### The image map

- Area attributes

Attribute	Value	Description
alt	text	Specifies an alternate text for an area
coords	coordinates	Specifies the coordinates of an area
href	URL	Specifies the destination of a link in an area
download	download	hyperlink is used for downloading a resource
shape	default rect circle poly	Specifies the shape of an area
target	_blank _parent _self _top	Specifies where to open the linked page specified in the href attribute

139

## Embedded Content

### The iframe element

- The **iframe** element represents a nested browsing context.
- The **src** attribute gives the address of a document that the nested browsing context is to contain.
- The **srcdoc** attribute gives the HTML content that the nested browsing context is to contain. The value of the attribute is the source of an iframe srcdoc document.
 

```
<iframe srcdoc=<p>Hello world!</p>
src="demo_iframe_srcdoc.htm"></iframe>
```
- The **name** attribute, if present, must be a valid browsing context name.
  - The given value is used to name the nested browsing context. When the browsing context is created, if the attribute is present, the browsing context name must be set to the value of this attribute; otherwise, the browsing context name must be set to the empty string.

141

## Embedded Content

### The iframe element

- The **sandbox** attribute, when specified, enables a set of extra restrictions on any content hosted by the iframe.
- The **width** and **height** attributes determine the horizontal and vertical dimensions, respectively.

```
<p>Example</p>
<iframe sandbox="allow-same-origin allow-forms allow-scripts" src=
"html26.html" width="400" height="500">
[Your user agent does not support frames or is currently configured
not to display frames.
However, you may visit <a href="foo.html">the related
document.</a>]
```

143

## Embedded Content

### The image map

- Coords attribute

This attribute specifies the position and shape on the screen. **The number and order of values depends on the shape being defined.** Possible combinations:

- rect: left-x, top-y, right-x, bottom-y.
- circle: center-x, center-y, radius.
- poly: x1, y1, x2, ..., xN, yN.

The first x and y coordinate pair and the last should be the same to close the polygon. When these coordinate values are not the same, user agents should infer an additional coordinate pair to close the polygon.

140

## Embedded Content

### The iframe element

```
<body>
<iframe src="html25.html" name="iframe_a">
<p>Your browser does not support iframes.</p>
</iframe>
<a href= "html26.html" target="iframe_a">Planets</a>
<p><b>Note:</b> Because the target of the link matches the name
of the iframe, the link will open in the iframe.</p>
</body>
</html>
```

142

## Embedded Content

### The embed element

- The **embed** element provides an integration point for an external (typically non-HTML) application or interactive content.
- The **src** attribute gives the address of the resource being embedded. The attribute, if present, must contain a valid non-empty URL potentially surrounded by spaces.
- The **type** attribute, if present, gives the MIME type by which the plugin to instantiate is selected.

```
<embed src="vowels.swf" width="720" height="500">
```

144

## Embedded Content

### The object element

- The **object** element can represent an external resource, which, depending on the type of the resource, will either be treated as an image, as a nested browsing context, or as an external resource to be processed by a plugin.
- The **data** attribute, if present, specifies the address of the resource.
- The **type** attribute, if present, specifies the type of the resource. If present, the attribute must be a valid MIME type.
- The **typemustmatch** attribute is a boolean attribute whose presence indicates that the resource specified by the data attribute is only to be used if the value of the type attribute and the Content-Type of the aforementioned resource match.

```
<object id="vowels" type="application/x-shockwave-flash"
       data="./wowels.swf" width="720" height="500">
  <param name="movie" value="./wowels.swf">
</object>
```

145

## Embedded Content

### The video element

- A **video** element is used for playing videos or movies, and audio files with captions.
- The video element is a media element whose media data is ostensibly video data, possibly with associated audio data.

```
<video width="320" height="240" src="movie.mp4"
      type="video/mp4" controls>
```

Your browser does not support the video tag.  
</video>

147

## Embedded Content

### The source element

- The **source** element allows authors to specify multiple alternative media resources for media elements. It does not represent anything on its own.
- The **src** attribute gives the address of the media resource. The **value** must be a valid non-empty URL potentially surrounded by spaces. This attribute must be present.

```
<video width="320" height="240" controls>
  <source src="movie.mp4" type="video/mp4">
  <source src="movie.ogg" type="video/ogg">
Your browser does not support the video tag.
</video>
```

149

## Embedded Content

### The param element

- The **param** element defines parameters for plugins invoked by object elements. It does not represent anything on its own.
- The **name** attribute gives the name of the parameter.
- The **value** attribute gives the value of the parameter.
- Both attributes must be present. They may have any value.

146

## Embedded Content

### The video element

Attribute	Value	Description
<b>autoplay</b>	autoplay	Specifies that the video will start playing as soon as it is ready
<b>controls</b>	controls	Specifies that video controls should be displayed (such as a play/pause button etc.)
<b>height</b>	pixels	Sets the height of the video player
<b>loop</b>	loop	Specifies that the video will start over again, every time it is finished
<b>muted</b>	muted	Specifies that the audio output of the video should be muted
<b>poster</b>	URL	Specifies an image to be shown while the video is downloading, or until the user hits the play button
<b>preload</b>	auto	Specifies if and how the author thinks the video should be loaded when the page loads. Metadata: only metadata. None: the browser should not load the video.
<b>src</b>	URL	Specifies the URL of the video file
<b>width</b>	pixels	Sets the width of the video player

## Embedded Content

### The audio element

- An **audio** element represents a sound or audio stream.
- Content may be provided inside the audio element. User agents should not show this content to the user; it is intended for older Web browsers which do not support audio, so that legacy audio plugins can be tried, or to show text to the users of these older browsers informing them of how to access the audio contents.

```
<audio controls>
  <source src= "applause.ogg" type="audio/ogg">
  <source src= "applause.mp3" type="audio/mpeg">
Your browser does not support the audio element.
</audio>
```

150

# HTML Links

151

## Links Introduction

- For **link** elements with an **href** attribute and a **rel** attribute, links must be created for the keywords of the rel attribute, as defined for those keywords in the link types section.
- Similarly, for **a** and **area** elements with an **href** attribute and a **rel** attribute, links must be created for the keywords of the rel attribute as defined for those keywords in the link types section.

153

## Links Link Types (attribute rel)

Rel type	Effect on... <u><a href="#">link</a></u>	Effect on... <u><a href="#">a</a></u> and <u><a href="#">area</a></u>	Brief description
<u><a href="#">alternate</a></u>	<u><a href="#">Hyperlink</a></u>	<u><a href="#">Hyperlink</a></u>	Gives alternate representations of the current document.
<u><a href="#">author</a></u>	<u><a href="#">Hyperlink</a></u>	<u><a href="#">Hyperlink</a></u>	Gives a link to the author of the current document or article.
<u><a href="#">bookmark</a></u>	<u><a href="#">not allowed</a></u>	<u><a href="#">Hyperlink</a></u>	Gives the permalink for the nearest ancestor section.
<u><a href="#">help icon</a></u>	<u><a href="#">Hyperlink</a></u> <u><a href="#">External Resource</a></u>	<u><a href="#">Hyperlink</a></u> <u><a href="#">not allowed</a></u>	Provides a link to context-sensitive help. Imports an icon to represent the current document.
<u><a href="#">license</a></u>	<u><a href="#">Hyperlink</a></u>	<u><a href="#">Hyperlink</a></u>	Indicates that the main content of the current document is covered by the copyright license described by the referenced document.
<u><a href="#">next</a></u>	<u><a href="#">Hyperlink</a></u>	<u><a href="#">Hyperlink</a></u>	Indicates that the current document is a part of a series, and that the next document in the series is the referenced document.

155

## Links Introduction

■ **Links** are a conceptual construct, created by **a**, **area**, and **link** elements, that represent a connection between two resources, one of which is the current Document. There are two kinds of links in HTML:

### ■ Links to external resources

■ These are links to resources that are to be used to augment the current document, generally automatically processed by the user agent.

### ■ Hyperlinks

■ These are links to other resources that are generally exposed to the user by the user agent so that the user can cause the user agent to navigate to those resources, e.g. to visit them in a browser or download them.

152

## Links Elements **<a>** and **<area>**

Attribute	Value	Description
<u><a href="#">download</a></u>	<u><a href="#">filename</a></u>	Specifies that the target will be downloaded when a user clicks on the hyperlink
<u><a href="#">href</a></u>	<u><a href="#">URL</a></u>	Specifies the URL of the page the link goes to
<u><a href="#">hreflang</a></u>	<u><a href="#">language_code</a></u>	Specifies the language of the linked document
<u><a href="#">rel</a></u>	<u><a href="#">alternate</a></u> <u><a href="#">author</a></u> <u><a href="#">bookmark</a></u> <u><a href="#">help</a></u> <u><a href="#">license</a></u> <u><a href="#">next</a></u> <u><a href="#">nofollow</a></u> <u><a href="#">noreferrer</a></u> <u><a href="#">prefetch</a></u> <u><a href="#">prev</a></u> <u><a href="#">search</a></u> <u><a href="#">tag</a></u>	Specifies the relationship between the current document and the linked document
<u><a href="#">target</a></u>	<u><a href="#">_blank</a></u> <u><a href="#">_parent</a></u> <u><a href="#">_self</a></u> <u><a href="#">_top</a></u> <u><a href="#">framename</a></u>	Specifies where to open the linked document
<u><a href="#">type</a></u>	<u><a href="#">Mime_type</a></u>	Specifies the Mime type of the linked document

154

## Links Link Types (attribute rel)

Rel type	Effect on... <u><a href="#">link</a></u>	Effect on... <u><a href="#">a</a></u> and <u><a href="#">area</a></u>	Brief description
<u><a href="#">nofollow</a></u>	<u><a href="#">not allowed</a></u>	<u><a href="#">Annotation</a></u>	Indicates that the current document's original author or publisher does not endorse the referenced document.
<u><a href="#">noreferrer</a></u>	<u><a href="#">not allowed</a></u>	<u><a href="#">Annotation</a></u>	Requires that the user agent not send an HTTP Referer (sic) header if the user follows the hyperlink.
<u><a href="#">prefetch</a></u>	<u><a href="#">External Resource</a></u>	<u><a href="#">External Resource</a></u>	Specifies that the target resource should be preemptively cached.
<u><a href="#">prev</a></u>	<u><a href="#">Hyperlink</a></u>	<u><a href="#">Hyperlink</a></u>	Indicates that the current document is a part of a series, and that the previous document in the series is the referenced document.
<u><a href="#">search</a></u>	<u><a href="#">Hyperlink</a></u>	<u><a href="#">Hyperlink</a></u>	Gives a link to a resource that can be used to search through the current document and its related pages.
<u><a href="#">stylesheet</a></u>	<u><a href="#">External Resource</a></u> <u><a href="#">not allowed</a></u>	<u><a href="#">Hyperlink</a></u>	Imports a stylesheet. Gives a tag (identified by the given address) that applies to the current document.

156

## HTML Table

- A **data cell** can contain text, images, lists, paragraphs, forms, tables, etc.
- If you do not specify a **border** attribute the table will be displayed without any borders
  - To display a table with borders, you will have to use the **border** attribute

Content Model:

Optionally a **caption** element, followed by zero or more **colgroup** elements, followed optionally by a **thead** element, followed optionally by a **tfoot** element, followed by either zero or more **tbody** elements or one or more **tr** elements, followed optionally by a **tfoot** element (but there can only be one **tfoot** element child in total), optionally intermixed with one or more script-supporting elements.

163

## HTML Table

```
<head>
<meta charset="utf-8" />
<title>The a element</title>
<style>
table { border-collapse: collapse; border: solid thick; }
colgroup, tbody { border: solid medium; }
td { border: solid thin; height: 1.4em; width: 1.4em; text-align: center; padding: 0; }
</style>
</head>
```

164

## HTML Table

```
<body>
<h1>Today's Sudoku</h1>
<table>
<colgroup><col><col><col>
<colgroup><col><col><col>
<colgroup><col><col><col>
<tbody>
<tr> <td> 1 <td> 3 <td> 6 <td> 4 <td> 7 <td> 9
<tr> <td> 2 <td> 9 <td> 1 <td> 7 <td> 8 <td> 5
<tr> <td> 7 <td> 5 <td> 2 <td> 6 <td> 3 <td> 8
<tr> <td> 2 <td> 4 <td> 3 <td> 9 <td> 6 <td> 1
<tr> <td> 5 <td> 9 <td> 7 <td> 2 <td> 4 <td> 8
<tr> <td> 6 <td> 8 <td> 1 <td> 5 <td> 3 <td> 2
```

165

## HTML Table

```
<tbody>
<tr> <td> 6 <td> 2 <td> 5 <td> 1 <td> 3 <td> 4
<tr> <td> 7 <td> 9 <td> 8 <td> 2 <td> 5 <td> 6
<tr> <td> 9 <td> 1 <td> 2 <td> 6 <td> 3 <td> 7
</tbody>
</body>
```

166

## HTML Table The colgroup element

- The **colgroup** element represents a group of one or more columns in the table that is its parent.
- If the colgroup element contains no col elements, then the element may have a span content attribute specified, whose value must be a valid non-negative integer greater than zero.
- The colgroup element and its span attribute take part in the table model.

167

## HTML Table The colgroup element

```
<table>
<colgroup>
<col span="2" style="background-color:red">
<col style="background-color:yellow">
</colgroup>
<tr> <th>ISBN</th> <th>Title</th> <th>Price</th> </tr>
<tr> <td>3476896</td> <td>My first HTML</td>
<td>$53</td> </tr>
<tr> <td>5869207</td> <td>My first CSS</td>
<td>$49</td> </tr>
</table>
```

168

## HTML Table (thead, tbody, tfoot)

- The **thead**, **tbody** and **tfoot** elements are used to group the header content, the body content and the footer content in an HTML table.
- Note: **<tfoot>** must appear before **<tbody>** within a table, so that a browser can render the foot before receiving all the rows of data.
- This division enables user agents to support scrolling of table bodies independently of the table head and foot.
  - When long tables are printed, the table head and foot information may be repeated on each page that contains table data.

169

## HTML Table (thead, tbody, tfoot)

```
<tbody>
  <tr>
    <td>January</td>
    <td>$100</td>
  </tr>
  <tr>
    <td>February</td>
    <td>$80</td>
  </tr>
</tbody>
</table>
</body>
```

171

## HTML Table

- Defining the style of a table

173

## HTML Table (thead, tbody, tfoot)

```
<body>
<table>
  <thead>
    <tr>
      <th>Month</th>
      <th>Savings</th>
    </tr>
  </thead>
  <tfoot>
    <tr>
      <td>Sum</td>
      <td>$180</td>
    </tr>
  </tfoot>
```

170

## HTML Table (rowspan and colspan)

- The td and th elements may have
  - rowspan** defines the number of rows a cell should span
  - colspan** defines the number of columns a cell should span

```
<table width="100%" border="1">
  <tr> <th>Month</th> <th>Amount</th> <th>Percentage</th> </tr>
  <tr> <td> January </td> <td colspan="2" rowspan="2" style="text-align: center;"></td> </tr>
  <tr> <td> February </td> <td>100</td> <td>10</td> </tr>
</table>
```

172

## HTML Forms

## HTML Forms

■ A **form** is a section of a document containing normal content, markup, special elements called **controls** and labels on those controls.

■ Controls:

- Buttons
- Checkboxes
- Radio buttons
- Menus
- Text input
- File select
- Hidden control
- Object controls

175

## HTML Forms

- Users generally "complete" a form by modifying its **controls** (entering text, selecting menu items, etc.), before submitting the form to an agent for processing (e.g., to a Web server, to a mail server, etc.)
- A control's "**control name**" is given by its **name** attribute.
  - The scope of the name attribute for a control within a form element is the form element.

176

## HTML Forms

Example:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="utf-8">
  <title>Pizza Ordering Form</title>
</head>
<form>
  <p><label>Customer name: <input></label></p>
  <p><label>Telephone: <input type="tel"></label></p>
  <p><label>E-mail address: <input type="email"></label></p>
```

177

## HTML Forms

```
<p><label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="900"></label></p>
<p><label>Delivery instructions:<br/> <textarea></textarea></label></p>
<p><button>Submit order</button></p>
</form>
</html>
```

179

<fieldset>

```
<legend> Pizza Size </legend>
<p><label> <input type="radio" name="size"> Small </label></p>
<p><label> <input type="radio" name="size"> Medium </label></p>
<p><label> <input type="radio" name="size"> Large </label></p>
</fieldset>
<fieldset>
<legend> Pizza Toppings </legend>
<p><label> <input type="checkbox"> Bacon </label></p>
<p><label> <input type="checkbox"> Extra Cheese </label></p>
<p><label> <input type="checkbox"> Onion </label></p>
<p><label> <input type="checkbox"> Mushroom </label></p>
</fieldset>
```

178

## HTML Forms Server Communication

Example:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="utf-8">
  <title>Pizza Ordering Form</title>
</head>
<form method="post" enctype="application/x-www-form-urlencoded" action="https://pizza.example.com/order.php">
  <p><label>Customer name: <input name="custname"></label></p>
  <p><label>Telephone: <input type="tel" name="custtel"></label></p>
  <p><label>E-mail address: <input type="email" name="custmail"></label></p>
```

180

## HTML Forms Server Communication

```
<fieldset>
<legend> Pizza Size </legend>
<p><label> <input type=radio name=size value="small"> Small
</label></p>
<p><label> <input type=radio name=size value="medium"> Medium
</label></p>
<p><label> <input type=radio name=size value="large"> Large
</label></p>
</fieldset>
```

181

## HTML Forms Server Communication

```
<p><label>Preferred delivery time: <input type=time min="11:00"
max="21:00" step="900" name="delivery"></label></p>
<p><label>Delivery instructions: <textarea
name="comments"></textarea></label></p>
<p><button>Submit order</button></p>
</form>
```

For example, if the customer entered "Denise Lawrence" as their name, "555-321-8642" as their telephone number, did not specify an e-mail address, asked for a medium-sized pizza, selected the Extra Cheese and Mushroom toppings, entered a delivery time of 7pm, and left the delivery instructions text field blank, the user agent would submit the following to the online Web service:

custname=Denise+Lawrence&custtel=555-321-  
8624&custemail=&size=medium&topping=cheese&topping=mushroom  
&delivery=19%3A00&comments=

183

## HTML Forms Client-side form validation

- It is also possible to limit the length of the input, using the maxlength attribute.

```
<p><label>Delivery instructions: <textarea name="comments"
maxlength=1000></textarea></label></p>
```

185

## HTML Forms Server Communication

```
<fieldset>
<legend> Pizza Toppings </legend>
<p><label> <input type=checkbox name="topping" value="bacon">
Bacon </label></p>
<p><label> <input type=checkbox name="topping" value="cheese">
Extra Cheese </label></p>
<p><label> <input type=checkbox name="topping" value="onion">
Onion </label></p>
<p><label> <input type=checkbox name="topping" value="mushroom">
Mushroom </label></p>
</fieldset>
```

182

## HTML Forms Client-side form validation

- Forms can be annotated in such a way that the user agent will check the user's input before the form is submitted.
- The simplest annotation is the **required** attribute, which can be specified on input elements to indicate that the form is not to be submitted until a value is given.

```
<p><label>Customer name: <input name="custname" required></label></p>
```

...

```
<legend> Pizza Size </legend>
<p><label> <input type=radio name=size required value="small"> Small
</label></p>
<p><label> <input type=radio name=size required value="medium"> Medium
</label></p>
<p><label> <input type=radio name=size required value="large"> Large
</label></p>
</fieldset>
```

..

```
<p><label>Preferred delivery time: <input type=time min="11:00" max="21:00"
step="900" name="delivery" required></label></p>
```

184

## HTML Forms

- The form element acts as a container for controls, by specifying:
  - The layout of the form** (given by the contents of the element).
  - The program that will handle** the completed and submitted form (the action attribute). The receiving program must be able to parse name/value pairs in order to make use of them.
  - The method by which user data** will be sent to the server (the method attribute).
  - A character encoding that must be accepted** by the server in order to handle this form (the accept-charset attribute). User agents may advise the user of the value of the accept-charset attribute and/or restrict the user's ability to enter unrecognized characters.

186

## HTML Forms

- In general, a control's "initial value" may be specified with the control element's **value** attribute.
- However, the initial value of a **textarea** element is given by its contents
- A control's initial value does not change.** Thus, when a form is reset, each control's current value is reset to its initial value

187

## HTML Forms

- If the method is "get", the user agent takes the value of **action**, appends a ? to it, then appends the form data set, encoded using the application/x-www-form-urlencoded content type. The user agent then traverses the link to this URI. In this scenario, form data are restricted to ASCII codes.
- If the method is "post", the user agent conducts an **HTTP post transaction** using the value of the **action** attribute and a message created according to the content type specified by the **enctype** attribute.

189

## HTML Forms: Control Types

- Checkboxes**
  - Checkboxes (and radio buttons) are on/off switches that may be toggled by the user. A switch is "on" when the control element's checked attribute is set.
  - When a form is submitted, only "on" checkbox controls can become successful.
  - Several checkboxes in a form may share the same control name.** Thus, for example, checkboxes allow users to select several values for the same property.
  - The **input** element is used to create a checkbox control.

191

## HTML Forms

### Attributes of the form element

Attribute	Value	Description
action	URL	Specifies where to send the form-data when a form is submitted
accept-charset	charset	Specifies the character-sets the server can handle for form-data
autocomplete	on, off	Specifies if the autofocus is on or off
enctype	application/x-www-form-urlencoded multipart/form-data text/plain	Specifies how form-data should be encoded before sending it to a server (multipart/form-data text/plain is only for POST)
method	get post	Specifies how to send form-data
name	name	Specifies the name for a form
novalidate	on, off	Specifies whether the form has to be validated or not
target	_blank new window _self same frame _top full body of the window framename in a named iframe	The target attribute specifies a name or a keyword that indicates where to display the response that is received after submitting the form.

## HTML Forms: Control Types

### Buttons types

- submit:** When activated, a submit button submits a form. A form may contain more than one submit button.
- reset:** When activated, a reset button resets all controls to their initial values.
- buttons:** Buttons have no default behavior.
  - Each button may have client-side scripts associated with the element's event attributes.

190

## HTML Forms: Control Types

### Radio Buttons

- Radio buttons are like checkboxes except that when several share the same control name, they are mutually exclusive: when one is switched "on", all others with the same name are switched "off".

- The **input** element is used to create a radio button control.

### Menus

- Menus offer users options from which to choose.
- The **select** element creates a menu, in combination with the **optgroup** and **option** elements.

192

## HTML Forms: Control Types

### Text input

- Authors may create two types of controls that allow users to input text.
- The `input` element creates a single-line input control and the `textarea` element creates a multi-line input control.
- In both cases, the input text becomes the control's current value

### File Select

- This control type allows the user to select files so that their contents may be submitted with a form.
- The `input` element is used to create a file select control.

193

194

## HTML Forms Input Element

### The `type` attribute of the Input Element

Keyword	State	Data type	Control type
<code>hidden</code>	<u>Hidden</u>	An arbitrary string	n/a
<code>text</code>	<u>Text</u>	Text with no line breaks	A text field
<code>search</code>	<u>Search</u>	Text with no line breaks	Search field
<code>tel</code>	<u>Telephone</u>	Text with no line breaks	A text field
<code>url</code>	<u>URL</u>	An absolute URL	A text field

195

196

## HTML Forms Input Element

### The `type` attribute

Keyword	State	Data type	Control type
<code>number</code>	<u>Number</u>	A numerical value	A text field or spinner control
<code>range</code>	<u>Range</u>	A numerical value, with the extra semantic that the exact value is not important	A slider control or similar
<code>color</code>	<u>Color</u>	An sRGB color with 8-bit red, green, and blue components	A color well
<code>checkbox</code>	<u>Checkbox</u>	A set of zero or more values from a predefined list	A checkbox

197

198

## HTML Forms: Control Types

### How are the control types implemented?

- `<input>` element
- `<button>` element
- `<select>` element
- `<datalist>` element
- `<optgroup>` element
- `<option>` element
- `<textarea>` element
- `<keygen>` element
- `<output>` element
- `<progress>` element
- `<meter>` element
- `<fieldset>` element
- `<legend>` element

194

## HTML Forms Input Element

### The `type` attribute

Keyword	State	Data type	Control type
<code>email</code>	<u>E-mail</u>	An e-mail address or list of e-mail addresses	A text field
<code>password</code>	<u>Password</u>	Text with no line breaks (sensitive information)	A text field that obscures data entry
<code>date</code>	<u>Date</u>	A date (year, month, day) with no time zone	A date control
<code>time</code>	<u>Time</u>	A time (hour, minute, seconds, fractional seconds) with no time zone	A time control

196

## HTML Forms Input Element

### The `type` attribute

Keyword	State	Data type	Control type
<code>radio</code>	<u>Radio Button</u>	An enumerated value	A radio button
<code>file</code>	<u>File Upload</u>	Zero or more files each with a <code>MIME type</code> and optionally a file name	A label and a button
<code>submit</code>	<u>Submit Button</u>	An enumerated value, with the extra semantic that it must be the last value selected and initiates form submission	A button
<code>image</code>	<u>Image Button</u>	A coordinate, relative to a particular image's size, with the extra semantic that it must be the last value selected and initiates form submission	Either a clickable image, or a button

198

## HTML Forms Input Element

### The `type` attribute

Keyword	State	Data type	Control type
<code>reset</code>	<u>Reset Button</u>	n/a	A button
<code>button</code>	<u>Button</u>	n/a	A button

199

## HTML Forms Input Element

### Some examples of specific attributes

- The `list` attribute is used to identify an element that lists predefined options suggested to the user.
- If present, its value must be the ID of a `datalist` element in the same document.

```
<label>Homepage: <input name=hp type=url list=hpurls></label>
<datalist id=hpurls>
<option value="http://www.google.com/" label="Google">
<option value="http://www.reddit.com/" label="Reddit">
</datalist>
```

201

## HTML Forms Input Element

### Some examples of specific attributes

- The `readonly` attribute is a boolean attribute that controls whether or not the user can edit the form control.
- The `required` attribute is a boolean attribute. When specified, the element is required.
- The `pattern` attribute specifies a regular expression against which the control's value, or, when the `multiple` attribute applies and is set, the control's values, are to be checked.
- The `min` and `max` attributes indicate the allowed range of values for the element.
- The `step` attribute indicates the granularity that is expected (and required) of the value, by limiting the allowed values.

203

## HTML Forms Input Element

### Input element attributes.

Different attributes depending on the specific value of `attribute type`.

List of attributes and their use can be found in the HTML5 specification

<http://www.w3.org/TR/html5/forms.html#the-input-element>

200

## HTML Forms Input Element

### Some examples of specific attributes

- The `placeholder` attribute represents a short hint (a word or short phrase) intended to aid the user with data entry when the control has no value.

```
<fieldset>
<legend>Mail Account</legend>
<p><label>Name: <input type="text" name="fullname" placeholder="John Ratenberger"></label></p>
<p><label>Address: <input type="email" name="address" placeholder="john@example.net"></label></p>
<p><label>Password: <input type="password" name="password"></label></p>
<p><label>Description: <input type="text" name="desc" placeholder="My Email Account"></label></p>
</fieldset>
```

202

## HTML Forms Input Element

### Example:

```
<form action="products.php" method="post" enctype="multipart/form-data">
<table>
<tr> <th> Product ID <th> Product name <th> Price <th> Action
<tr>
<td> <input readonly="readonly" name="1.pid" value="H412">
<td> <input required="required" name="1.pname" value="Floor lamp Ulke">
<td> $<input required="required" type="number" min="0" step="0.01" name="1.pprice" value="49.99">
<td> <button formnovalidate="formnovalidate" name="action" value="delete:1">Delete</button>
</tr>
```

204

## HTML Forms Input Element

```
<td> <input readonly="readonly" name="2.pid" value="FG28">
<td> <input required="required" name="2.pname" value="Table lamp Ulke">
<td> $<input required="required" type="number" min="0" step="0.01" name="2.pprice" value="24.99">
<td> <button formnovalidate="formnovalidate" name="action" value="delete:2">Delete</button>
```

205

## HTML Forms Input Element

```
<tr>
<td> <input required="required" name="3.pid" value="" pattern="[A-Z0-9]+>
<td> <input required="required" name="3.pname" value="">
<td> $<input required="required" type="number" min="0" step="0.01" name="3.pprice" value="">
<td> <button formnovalidate="formnovalidate" name="action" value="delete:3">Delete</button>
</table>
<p> <button formnovalidate="formnovalidate" name="action" value="add">Add</button> </p>
<p> <button name="action" value="update">Save</button> </p>
</form>
```

206

## HTML Forms Input Element

### Some examples of specific attributes

- The **multiple** attribute is a boolean attribute that indicates whether the user is to be allowed to specify more than one value.
  - The multiple attribute works with the following input types: email, and file.
  - For `<input type="file">`: to select multiple files, hold down the CTRL or SHIFT key while selecting.
  - For `<input type="email">`: separate each email with a comma, like: mail@example.com, mail2@example.com, mail3@example.com in the email field.

```
<form action="demo_form.php">
  Select images: <input type="file" name="img" multiple>
  <input type="submit">
</form>
```

207

## HTML Forms Button Element

### Main attributes of the button element

- autofocus**: allows the author to indicate that a control is to be focused as soon as the page is loaded, allowing the user to just start typing without having to manually focus the main control.
- disabled**
- form**: to explicitly associate the button element with its form owner (the value is the ID of the form)
- formnovalidate**: indicates that the form is not to be validated during submission
- value**: The value attribute gives the element's value for the purposes of form submission. The element's value is the value of the element's value attribute, if there is one, or the empty string otherwise.

209

## HTML Forms Button Element

- Buttons created with the **button** element function just like buttons created with the **input** element, but they offer richer rendering possibilities:
  - the **button** element may have content. For example, a button element that contains an image functions like and may resemble an input element whose type is set to "image", but the button element type allows content.
  - Always specify the type attribute for the button: submit, reset, button (does nothing).

208

## HTML Forms Button Element

```
<form action="http://somesite.com/prog/adduser" method="post">
  First name: <input type="text" name="firstname"><br>
  Last name: <input type="text" name="lastname"><br>
  email: <input type="text" name="email"><br>
  <input type="radio" name="sex" value="Male"> Male<br>
  <input type="radio" name="sex" value="Female"> Female<br>
  <button name="submit" value="submit" type="submit"> Send
  </button>
  <button name="reset" type="reset">Reset
  </button>
</p>
</form>
```

210

## HTML Forms

### select, optgroup and option elements

- The **select** element creates a menu.
  - Each choice offered by the menu is represented by an **option** element.
  - A select element must contain at least one option element.
- The **optgroup** element allows authors to group choices logically. The label value gives the name of the group.
  - Helpful when the user must choose from a long list of options; groups of related choices are easier to grasp and remember than a single long list of options.
- The **option** element represents an option in a select element or as part of a list of suggestions in a datalist element. The selected attribute represents the default selectedness of the element

211

## HTML Forms

### select, optgroup and option elements

- When rendering a menu choice, **user agents should use the value of the label attribute of the option element as the choice.**
  - If this attribute is not specified, user agents should use the contents of the option element.
- The **label attribute of the optgroup element** specifies the label for a group of choices
- Only selected options will be successful (using the control name "c" in the following example).
- When no options are selected, the control is not successful and neither the name nor any values are submitted to the server when the form is submitted.

213

## HTML Forms

### select, optgroup and option elements

```
<option value="8.02.1">Lecture 01: What holds our world together?
<option value="8.02.2">Lecture 02: Electric Field
<option value="8.02.3">Lecture 03: Electric Flux
<optgroup label="8.03 Physics III: Vibrations and Waves">
<option value="8.03.1">Lecture 01: Periodic Phenomenon
<option value="8.03.2">Lecture 02: Beats
<option value="8.03.3">Lecture 03: Forced Oscillations with Damping
</select>
</label>
<p><input type="submit" value="Play">
</form>
```

215

## HTML Forms

### select, optgroup and option elements

- <select> attributes
  - disabled – specifies that a drop-down list should be disabled
  - multiple – specifies that multiple options can be selected
  - size – gives the number of options to show to the user
  - required – the user is required to select a value

212

## HTML Forms

### select, optgroup and option elements

- Example of the <optgroup> element

```
<form action="http://www.watch.com/watch.php" method="get">
<p>Which course would you like to watch today?
<p><label>Course:
<select name="c">
<optgroup label="8.01 Physics I: Classical Mechanics">
<option value="8.01.1">Lecture 01: Powers of Ten
<option disabled value="8.01.2">Lecture 02: 1D Kinematics
<option value="8.01.3">Lecture 03: Vectors
<optgroup disabled label="8.02 Electricity and Magnetism">
```

214

## HTML Forms

### Textarea element

- The textarea element **creates a multi-line text input control**. User agents should use the contents of this element as the initial value of the control and should render this text initially.
- The **cols** and **rows** attribute specify the expected maximum number of characters per line and the number of lines to show, respectively.
- The **maxlength** attribute specifies the allowed maximum length.

216

## HTML Forms Textarea element

```
<form action="http://www.elaborate.com/elab.php"
      method="get">
<p>
<textarea name="thetext" rows="10" cols="80"
          maxlength="20">
</textarea>
<input type="submit" value="Send">
<input type="reset" value="Reset"></p>
</form>
```

217

## HTML Forms Label element

- The **label** element represents a caption in a user interface.
- The caption can be associated with a specific form control, known as the label element's labeled control, either using the **for** attribute, or by putting the form control inside the label element itself.
- The **for** attribute explicitly associates the label being defined with another control. When present, the value of this attribute must be the same as the value of the **id** attribute of some other control in the same document. When absent, the label being defined is associated with the element's contents.
- More than one label may be associated with the same control by creating multiple references via the **for** attribute.
- When a **LABEL** element receives focus, it passes the focus on to its associated control.

219

## HTML Forms Label element

- To associate a label with another control implicitly, the control element must be within the contents of the label element.
  - In this case, the label may only contain one control element.
  - The label itself may be positioned before or after the associated control.

```
<form action="..." method="post">
<p><label>First Name <input type="text"
      name="firstname"></label>
<label><input type="text" name="lastname"> Last
      Name</label></p>
</form>
```

221

## HTML Forms Label element

- Some form controls automatically have labels associated with them (press buttons) while most do not (text fields, checkboxes and radio buttons, and menus).
- For those controls that have implicit labels, user agents should use the value of the "value" attribute as the label string.
- The **label** element is used to specify labels for controls that do not have implicit labels.

218

## HTML Forms Label element

```
<form action="http://somesite.com/prog/adduser" method="post">
<p><label for="firstname">First name:</label> <input type="text"
      id="firstname"><br>

<input type="radio" name="sex" value="Female"> Female<br>
<input type="submit" value="Send"> <input type="reset"></p>
</form>
```

220

## HTML Forms Focus to an element

- There are several ways to give focus to an element:
  - Designate the element with a pointing device.
  - Navigate from one element to the next with the keyboard.
    - The document's author may define a **tabbing order** that specifies the order in which elements will receive focus if the user navigates the document with the keyboard. Once selected, an element may be activated by some other key sequence.
  - Select an element through an **access key** (sometimes called "keyboard shortcut" or "keyboard accelerator").

222

## HTML Forms Tabbing navigation

### `tabindex = number`

- The `tabindex` attribute specifies the position of the current element in the tabbing order for the current document.
  - Number is between 0 and 32767.
  - Values **need not be sequential** nor must they begin with any particular value.
  - The tabbing order may include elements nested within other elements.
  - The following elements support the `tabindex` attribute: `a`, `area`, `button`, `input`, `object`, `select`, and `textarea`.

223

## HTML Forms Tabbing navigation

```
<p>Go to the <a tabindex="20"
href="http://www.w3.org/">W3C Web site. </a> ...some
more... <button type="button" name=
"get-database" tabindex="18" onclick="get-
database">Get the
current database.</button> ...some more...</p>
<form action="..." method="post">
<p><input tabindex="1" type="text" name="field1">
<input tabindex="1" type="text" name="field2"> <input
tabindex=
"2" type="submit" name="submit"></p>
</form>
```

225

## HTML Forms Access key

- ```
<form action="..." method="post">
<p><label for="fuser" accesskey="u">User
Name</label>
<input type="text" name="user" id="fuser"></p>
</form>
```
- The invocation of access keys depends on the underlying system. For instance, on machines running MS Windows, one generally has to press the "alt" key in addition to the access key. On Apple systems, one generally has to press the "cmd" key in addition to the access key.

227

## HTML Forms Tabbing navigation

- Elements should be navigated by user agents according to the following rules:
  1. First, elements that **support the `tabindex` attribute and assign a positive value to it** are navigated:
    - from the element with the lowest `tabindex` value to the element with the highest value in the order they appear in the character stream if have identical `tabindex` values
  2. Then, elements that **do not support the `tabindex` attribute or support it and assign it a value of "0"** are **navigated next**. These elements are navigated in the order they appear in the character stream.
  3. Elements that **are disabled** do not participate in the tabbing order.

224

## HTML Forms Access key

### `accesskey = character`

- This attribute assigns an access key to an element. An access key is a single character from the document character set.
- Pressing an access key assigned to an element gives focus to the element. The action that occurs when an element receives focus depends on the element.
- The following elements support the `accesskey` attribute: `a`, `area`, `button`, `input`, `label`, `legend`, and `textarea`

226

## HTML Forms Disabled controls

### Disabled

- When set for a form control, this boolean attribute disables the control for user input.
  - Disabled controls do not receive focus
  - Disabled controls are skipped in tabbing navigation
  - Disabled controls cannot be successful.
- The following elements support the `disabled` attribute: `button`, `input`, `optgroup`, `option`, `select` and `textarea`.

228

## HTML Forms readonly controls

### Readonly

- When set for a form control, this boolean attribute prohibits changes to the control.
  - Read-only elements receive focus but cannot be modified by the user.
  - Read-only elements are included in tabbing navigation
  - Read-only elements may be successful
- The following elements support the readonly attribute: **input** and **textarea**.

```
<input readonly name="fred" value="stone">
```

229

## HTML Forms Form submission

- **Menus:** the control name is provided by a select element and values are provided by option elements. **Only selected options may be successful.** When no options are selected, the control is not successful and neither the name nor any values are submitted to the server when the form is submitted.
- **File select:** The current value of a file select is a list of one or more file names. Upon submission of the form, the contents of each file are submitted with the rest of the form data. The file contents are packaged according to the form's content type.
- **Object control:** The current value of an object control is determined by the object's implementation

231

## HTML Forms Form submission

- ```
<form action="..." method="post">
<p><input type="password" style="display:none"
  name=
  "invisible-password" value="mypassword"></p>
</form>
```
- will still cause a value to be paired with the name "invisible-password" and submitted with the form
- Note: this mechanism affords only light security protection. Although the password is masked by user agents from casual observers, it is transmitted to the server in clear text.

233

## HTML Forms Form submission

- A **successful control** is "valid" for submission. Every successful control has its control name paired with its current value as part of the submitted form data set.
- Note that
  - Controls that are disabled cannot be successful.
  - **Submit button:** If a form contains more than one submit button, only the activated submit button is successful.
  - **Checkboxes:** All "on" checkboxes may be successful.
  - **Radio Buttons:** For radio buttons that share the same value of the name attribute, **only the "on" radio button may be successful.**

230

## HTML Forms Form submission

- If a control does not have a current value when the form is submitted, user agents are not required to treat it as a successful control.
- Furthermore, user agents should not consider the following controls successful:
  - Reset buttons.
  - object elements whose declare attribute has been set.
- **Hidden controls and controls that are not rendered because of style sheet settings may still be successful.** For example

232

## HTML Forms Form submission

The user agent processes a form as follows:

### 1. Identify the successful controls

### 2. Build a form data set

A **form data set** is a sequence of control-name /current-value pairs constructed from successful controls

### 3. Encode the form data set

The form data set is then **encoded** according to the **content type** specified by the enctype attribute of the FORM element.

### 4. Submit the encoded form data set

### 5. Send to the Processing agent

The encoded data is sent to the processing agent designated by the action attribute using the protocol specified by the method attribute.

234

## HTML Forms Processing form data

## HTML Forms

### Processing form data

HTML 5 user agents must support the established conventions in the following cases:

- **Method = "get" and action = HTTP URI**
  - The user agent
    - takes the value of action,
    - appends a '?' to it,
    - appends the form data set, encoded using the "application/x-www-form-urlencoded" content type.
  - The user agent then traverses the link to the specified URI.
    - In this scenario, form data are restricted to ASCII codes.

235

## HTML Forms

### Processing form data

- **Method = "post" and action = HTTP URI**
  - The user agent conducts an HTTP "post" transaction using the value of the action attribute and a message created according to the content type specified by the enctype attribute.
- For any other value of action or method, behavior is unspecified.

237

## HTML Forms

### Form content type

#### ■ multipart/form-data

This content type should be used for submitting forms that contain files, non-ASCII data, and binary data.

A "multipart/form-data" message contains a series of parts, each representing a successful control. The parts are sent to the processing agent in the same order the corresponding controls appear in the document stream.

Each part has an optional "Content-Type" header that defaults to "text/plain". User agents should supply the "Content-Type" header, accompanied by a "charset" parameter.

239

## HTML Forms

### Processing form data

Example method "get"

```
<form action="/find.php" method="get">
<input type="text name=t">
<input type="search name=q">
<input type="submit">
</form>
```

- The user agent will load /find.php?t=cats&q=fur.

236

## HTML Forms

### Form content type

- The enctype attribute of the FORM element specifies the content type used to encode the form data set for submission to the server.

#### ■ application/x-www-form-urlencoded

This is the default content type. Forms submitted with this content type must be encoded as follows:

- Control names and values are escaped. Space characters are replaced by '+', and then reserved characters are escaped: Non-alphanumeric characters are replaced by '%HH', a percent sign and two hexadecimal digits representing the ASCII code of the character. Line breaks are represented as "CR LF" pairs (i.e., '%0D%0A').
- The control names/values are listed in the order they appear in the document. The name is separated from the value by '=' and name/value pairs are separated from each other by '&'.

238

## HTML Forms

### Form content type

#### ■ multipart/form-data (continued)

Each part is expected to contain:

- a "Content-Disposition" header whose value is "form-data".
- a name attribute specifying the control name of the corresponding control.

Thus, for example, for a control named "mycontrol", the corresponding part would be specified:

Content-Disposition: form-data; name="mycontrol"

As with all MIME transmissions, "CR LF" (i.e., '%0D%0A') is used to separate lines of data.

240

## HTML Forms

### Form content type

Suppose we have the following form:

```
<form action="http://server.com/cgi/handle" enctype=
  "multipart/form-data" method="post">
<p>What is your name? <input type="text"
  name="submit-name"><br>
What files are you sending? <input type="file"
  name="files"><br>
<input type="submit" value="Send"> <input
  type="reset"></p>
</form>
```

241

## HTML Forms

### Form content type

The user agent might send back:

```
Content-Type: multipart/form-data; boundary=AaB03x
--AaB03x
Content-Disposition: form-data; name="submit-name"
Larry
--AaB03x
Content-Disposition: form-data; name="files";
filename="file1.txt"
Content-Type: text/plain
... contents of file1.txt ...
--AaB03x--
```

242

## HTML Forms

### Form content type

If the user selected a second (image) file "file2.gif":

```
Content-Type: multipart/form-data; boundary=AaB03x
--AaB03x
Content-Disposition: form-data; name="submit-name"
Larry
--AaB03x
Content-Disposition: form-data; name="files"
Content-Type: multipart/mixed; boundary=BbC04y
```

243

## Checking Forms

### with validation

- Form validation is an optimization because it alone is not sufficient to guarantee that forms submitted to the server are correct and valid.
- It is an optimization because it is designed to help a web application fail fast. In other words, it is better to notify a user that a page contains invalid form controls right inside the page, using the browser's built-in processing.

245

## HTML Forms

### Form content type

```
--BbC04y
Content-Disposition: file; filename="file1.txt"
Content-Type: text/plain
... contents of file1.txt ...
--BbC04y
Content-Disposition: file; filename="file2.gif"
Content-Type: image/gif
Content-Transfer-Encoding: binary
...contents of file2.gif...
--BbC04y--
--AaB03x--
```

244

## Checking Forms

### with validation

- HTML5 does introduce eight handy ways to enforce correctness on form control entry.
  - Object ValidityState allows accessing their status
- ```
var valCheck = document.myForm.myInput.validity;
valCheck contains a reference to the ValidityState object of the
form element named myInput.
```

#### valCheck.valid

returns a Boolean value which informs us whether or not all validity constraints are currently met on this particular form control.

If all eight constraints are passing, the valid flag will be true. Otherwise, if any of the validity constraints fail, the valid attribute will be false.

246

## Checking Forms Validity constraints (1)

### The valCheck.valueMissing Constraint

- **Purpose:** Ensure that some value is set on this form control
- **Usage:** Set the required attribute on the form control to true
- **Usage example:** <input type="text" name="myText" required>
- **Details:** If the required attribute is set on a form control, the control will be in an invalid state unless the user or a programmatic call sets some value to the field. For example, a blank text field will fail a required check, but will pass as soon as any text is entered. When blank, the valueMissing will return true.

247

## Checking Forms Validity constraints (2)

### The valCheck.typeMismatch Constraint

- **Purpose:** Guarantee that the type of the value matches expectations (number, email, URL, and so on)
- **Usage:** Specify one of the appropriate type attributes on the form control
- **Usage example:** <input type="email" name="myEmail">
- **Details:** Special form control types aren't just for customized phone keyboards! If your browser can determine that the value entered into a form control doesn't conform to the rules for that type—for example, an email address without an @ symbol—the browser can flag this control as having a type mismatch. Another example would be a number field that cannot parse to a valid number. In either case, the typeMismatch will return true.

248

## Checking Forms Validity constraints (3)

### The valCheck.patternMismatch Constraint

- **Purpose:** Enforce any pattern rule set on a form control which details specific valid formats
- **Usage:** Set the pattern attribute on the form control with the appropriate pattern
- **Usage example:** <input type="text" name="creditcardnumber" pattern="[0-9]{16}" title="A credit card number is 16 digits with no spaces or dashes">
- **Details:** The pattern attribute gives developers a powerful and flexible way of enforcing a regular expression pattern on the value of a form control. When a pattern is set on a control, the patternMismatch will return true whenever the value does not conform to the rules of the pattern. To assist users and assistive technology, you should set the title on any pattern-controlled field to describe the rules of the format.

249

## Checking Forms Validity constraints (4)

### The valCheck.tooLong Constraint

- **Purpose:** Make sure that a value does not contain too many characters
- **Usage:** Put a maxLength attribute on the form control
- **Usage example:** <input type="text" name="limitedText" maxLength="140">
- **Details:** This humorously-named constraint will return true if the value length exceeds the maxLength. While form controls will generally try to enforce the maximum length during user entry, certain situations including programmatic settings can cause the value to exceed the maximum.

250

## Checking Forms Validity constraints (5)

### The valCheck.rangeUnderflow Constraint

- **Purpose:** Enforce the minimum value of a numeric control
- **Usage:** Set a min attribute with the minimum allowed value
- **Usage example:** <input type="range" name="ageCheck" min="18">
- **Details:** In any form controls that do numeric-range checking, it is possible for the value to get temporarily set below the allowable range. In these cases, the ValidityState will return true for the rangeUnderflow field.

251

## Checking Forms Validity constraints (6)

### The valCheck.rangeOverflow Constraint

- **Purpose:** Enforce the maximum value of a numeric control
- **Usage:** Set a max attribute with the maximum allowed value
- **Usage example:** <input type="range" name="kidAgeCheck" max="12">
- **Details:** Similar to its counterpart rangeUnderflow, this validity constraint will return true if the value of a form control becomes greater than the max attribute.

252

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Checking Forms Event Handler for Invalid Events (Ex.)

```
function invalidHandler(evt) {
    // find the label for this form control
    var label =
        evt.target.parentElement.getElementsByTagName("label")[0];
    // set the label's text color to red
    label.style.color = 'red';
    // stop the event from propagating higher
    evt.stopPropagation();
    // stop the browser's default handling of the validation error
    evt.preventDefault();
}

// register an event listener for "invalid" events
myField.addEventListener("invalid", invalidHandler, false);
```

259

CANVAS

260

## Canvas

- The canvas element provides scripts with a resolution-dependent bitmap canvas, which can be used for rendering graphs, game graphics, art, or other visual images on the fly.
- Authors should not use the canvas element in a document when a more suitable element is available.
- Two attributes to control the size of the element's bitmap: `width` and `height`.
- The HTML5 Canvas API supports the same two-dimensional drawing operations that most modern operating systems and frameworks support.
  - To programmatically use a canvas, you have to first get its context. You can then perform actions on the context and finally apply those actions to the context.

261

## Canvas Checking for support

```
try {
    document.createElement("canvas").getContext("2d");
} catch (e) {
    alert("HTML5 Canvas is not supported in your browser.");
}
```

263

### ■ Canvas definition

<canvas>  
 Update your browser to enjoy canvas!  
 </canvas>

CSS can be applied to the canvas element itself to add borders, padding, margins, etc.  
 Additionally, some CSS values are inherited by the contents of the canvas; fonts are a good example, as fonts drawn into a canvas default to the settings of the canvas element itself.  
 Furthermore, properties set on the context used in canvas operations follow the CSS syntax. Colors and fonts, for example, use the same notation on the context that they use throughout any HTML or CSS document.

262

## Canvas Draw a Diagonal line

```
<!DOCTYPE html>
<html>
    <title>Diagonal line example</title>
    <canvas id="diagonal" style="border: 1px solid;" width="200" height="200"> </canvas>
    <script>
        function drawDiagonal() {
            // Get the canvas element and its drawing context
            var canvas = document.getElementById('diagonal');
            var context = canvas.getContext('2d');
```

264

Università di Pisa

Francesco Marcellini

# Canvas

## Draw a Diagonal line

```
// Create a path in absolute coordinates
    context.beginPath();      //start a new path
    context.moveTo(70, 140);  //move the context point
    context.lineTo(140, 70);  //draw straight lines
    context.lineWidth = 15;
    context.strokeStyle = '#ff0000'; //set the color
    context.lineCap = 'round'; //butt, round, square
    // Stroke the line onto the canvas (makes the line visible)
    context.stroke();
}
window.addEventListener("load", drawDiagonal, true);
</script>
</html>
```

265

The diagram illustrates the process of applying transformations from drawing operations at the origin to the final drawing on the canvas. It shows a sequence of steps:

- Drawing operations at origin:** A box contains code: `context.beginPath(); context.moveTo(0, 0); context.lineTo(70, -70); context.stroke();`. An arrow points from this box to a point labeled "Origin (0, 0)" on a grid.
- Browser transformation implementation:** An arrow points from the "Drawing operations at origin" box to a box containing the code: `context.translate(100, 100);`.
- New coordinates 100, 100:** An arrow points from the "Browser transformation implementation" box to a point on the grid labeled "New coordinates 100, 100".
- Final drawing on canvas:** The final result is shown as a large circle with a gray gradient and a black outline, centered at the new coordinates (100, 100) on the grid.

Università di Pisa

Francesco Marcellini

# Canvas

## Draw a Diagonal line

```
function drawDiagonal() {  
    var canvas = document.getElementById('diagonal');  
    var context = canvas.getContext('2d');  
    // Save a copy of the current drawing state  
    context.save();  
    // Move the drawing context to the right, and down  
    context.translate(70, 140);  
    // Draw the same line as before, but using the origin as a start  
    context.beginPath();  
    context.moveTo(0, 0);  
    context.lineTo(70, -70);  
    context.stroke();  
    // Restore the old drawing state  
    context.restore();  
}
```

267

# Canvas

## Draw a Diagonal line

### Why context.save()?

- If you do not save the state, the modifications you're making during the operation (translate, scale, and so on) will continue to be applied to the context in future operations, and that might not be desirable.
- At the end, **you restore the context to its clean original state**, so that future canvas operations are performed without the translation that was applied in this operation.

*Francesco Marcellini*

# Canvas Working with Paths

```
function createCanopyPath(context) {  
    // Draw the tree canopy  
    context.beginPath();  
    context.moveTo(-25, -50); context.lineTo(-10, -80); context.lineTo(-20, -80);  
    context.lineTo(-5, -110); context.lineTo(-15, -110);  
    // Top of the tree  
    context.lineTo(0, -140); context.lineTo(15, -110);  
    context.lineTo(5, -110); context.lineTo(20, -80);  
    context.lineTo(10, -80); context.lineTo(25, -50);  
    // Close the path back to its start point  
    context.closePath();  
}  
  
closePath -> similar to lineTo but the destination is assumed to be the  
origination of the path
```

269

The slide features a decorative graphic in the top-left corner consisting of overlapping colored squares (yellow, red, blue) and a black crosshair. The title 'Canvas Working with Paths' is centered in large blue letters. Below the title is a block of JavaScript code demonstrating how to draw canopy paths on a canvas.

```
function drawTrails() {  
    var canvas = document.getElementById('trails');  
    var context = canvas.getContext('2d');  
    context.save();  
    context.translate(130, 250);  
    // Create the shape for our canopy path  
    createCanopyPath(context);  
    // Stroke the current path  
    context.stroke();  
    context.restore();  
}  
window.addEventListener("load", drawTrails, true);
```

A watermark of the University of Pisa seal is visible in the bottom-left corner, and a small green play button icon is in the bottom-right corner.

## Canvas Working with Styles

```
// Increase the line width
context.lineWidth = 4;

// Round the corners at path joints
context.lineJoin = 'round';

// Change the color to brown
context.strokeStyle = '#663300';

// Set the fill color to green and fill the canopy
context.fillStyle = '#339900';
context.fill();
```

271

## Canvas Drawing Curves

```
context.quadraticCurveTo(xC, yC, xS, yS);
```

(xC,yC) – coordinates of the control point. The control point sits to the side of the curve (not on it) and acts almost as a gravitational pull for the points along the curve path. By adjusting the location of the control point, you can adjust the curvature of the path you are drawing.

(xS,yS) – final stop in the curve

273

## Canvas Inserting Images into a Canvas

- Images can be stamped, stretched, modified with transformations, and often be the focus of the entire canvas.
- But images also add a complication to the canvas operations: you must wait for them to load.
- The image has to be loaded completely before you attempt to render it.

### Solution

```
// Load the bark image
var bark = new Image();
bark.src = "bark.jpg";
// Once the image is loaded, draw on the canvas
bark.onload = function () {
drawTrails();
}
```

275

## Canvas Working with Styles

```
// Change fill color to brown
context.fillStyle = '#663300';

// Fill a rectangle for the tree trunk
context.fillRect(-5, -50, 10, 50);

// takes the x and y location as well as the width and the height
```

272

## Canvas Drawing Curves

```
// Save the canvas state and draw the path
context.save();
context.translate(-10, 350);
context.beginPath();
// The first curve bends up and right
context.moveTo(0, 0);
context.quadraticCurveTo(170, -50, 260, -190);
// The second curve continues down and right
context.quadraticCurveTo(310, -250, 410, -250);
// Draw the path in a wide brown stroke
context.strokeStyle = '#663300';
context.lineWidth = 20;
context.stroke();
// Restore the previous canvas state
context.restore();
```

274

## Canvas Inserting Images into a Canvas

### Drawing an image on a canvas

```
// Draw the bark pattern image where
// the filled rectangle was before
context.drawImage(bark, -5, -50, 10, 50);
x y width height
```

This option will scale the image to fit into the  $10 \times 50$  pixel space that we have allocated for our trunk.

276

## Canvas Using Gradients

- Gradients allow you to apply a gradual algorithmic sampling of colors as either a stroke or fill style
- Creating gradients requires a three-step process:
  1. Create the gradient object itself.
  2. Apply color stops to the gradient object, signaling changes in color along the transition.
  3. Set the gradient as either a fillStyle or a strokeStyle on the context.
- If you supply points A and B as the arguments to the creation of a gradient, the color will be transitioned for any stroke or fill that moves in the direction of point A to point B.

277

## Canvas Using Gradients

```
// A second, vertical gradient creates a shadow from the
// canopy on the trunk
var canopyShadow = context.createLinearGradient(0, -50, 0, 0);
// The beginning of the shadow gradient is black, but with
// a 50% alpha value
canopyShadow.addColorStop(0, 'rgba(0, 0, 0, 0.5)');
// Slightly further down, the gradient completely fades to
// fully transparent. The rest of the trunk gets no shadow.
canopyShadow.addColorStop(0.2, 'rgba(0, 0, 0, 0.0)');
// Draw the shadow gradient on top of the trunk gradient
context.fillStyle = canopyShadow;
context.fillRect(-5, -50, 10, 50);
```

279

## Canvas Using Background Patterns

### Repetition Patterns

Repeat	Value
repeat	(Default) The image is repeated in both directions
repeat-x	The image is repeated only in the X dimension
repeat-y	The image is repeated only in the Y dimension
no-repeat	The image is displayed once and not repeated

281

## Canvas Using Gradients

```
// Create a 3 stop gradient horizontally across the trunk
var trunkGradient = context.createLinearGradient(-5, -50, 5, -50);
// The beginning of the trunk is medium brown
trunkGradient.addColorStop(0, '#663300');
// The middle-left of the trunk is lighter in color
trunkGradient.addColorStop(0.4, '#996600');
// The right edge of the trunk is darkest
trunkGradient.addColorStop(1, '#552200');
// Apply the gradient as the fill style, and draw the trunk
context.fillStyle = trunkGradient;
context.fillRect(-5, -50, 10, 50);
```

278

## Canvas Using Background Patterns

- The HTML5 Canvas API also includes an option to set an image as a repeatable pattern for either a path stroke or fill.
 

```
// Replace the bark image with
// a trail gravel image
var gravel = new Image();
gravel.src = "gravel.jpg";
gravel.onload = function () {
  drawTrails();
}

// Replace the solid stroke with a repeated
// background pattern
context.strokeStyle = context.createPattern(gravel, 'repeat');
context.lineWidth = 20;
context.stroke();
```

280

## Canvas Scaling Canvas Objects

```
// Move tree drawing into its own function for reuse
function drawTree(context) {
  var trunkGradient = context.createLinearGradient(-5, -50, 5, -50);
  ...

  // Draw the second tree at X=260, Y=500
  context.save();
  context.translate(260, 500);
  // Scale this tree twice normal in both dimensions
  context.scale(2, 2);
  drawTree(context);
  context.restore();
```

282

## Canvas Scaling Canvas Objects

Note: transforms such as `scale` and `rotate` operate from the origin.

- If you perform a rotate transform to a shape drawn off origin, a rotate transform will rotate the shape around the origin rather than rotating in place.
- Similarly, if you performed a scale operation to shapes before translating them to their proper position, all locations for path coordinates would also be multiplied by the scaling factor.
- Depending on the scale factor applied, this new location could even be off the canvas altogether, leaving you wondering why your scale operation just 'deleted' the image.

283

## Canvas Scaling Canvas Objects

Example (continued)

```
// Create a slanted tree as the shadow by applying
// a shear transform, changing X values to increase
// as Y values increase
context.transform(1, 0,-0.5, 1, 0, 0);
// Shrink the shadow down to 60% height in the Y dimension
context.scale(1, 0.6);
// Set the tree fill to be black, but at only 20% alpha
context.fillStyle = 'rgba(0, 0, 0, 0.2)';
context.fillRect(-5, -50, 10, 50);
// Redraw the tree with the shadow effects applied
createCanopyPath(context);
context.fill();
// Restore the canvas state
context.restore();
```

285

## Canvas Using Canvas Text

The text drawing routines consist of two functions on the context object:

- `fillText (text, x, y, maxWidth)`
- `strokeText (text, x, y, maxWidth)`

Both functions take the text as well as the location at which it should be drawn.

Optionally, a `maxwidth` argument can be provided to constrain the size of the text by automatically shrinking the font to fit the given size.

In addition, a `measureText` function is available to return a metrics object containing the width of the given text should it be rendered using the current context settings.

287

## Canvas Scaling Canvas Objects

```
context.save();
// rotation angle is specified in radians
context.rotate(1.57);
context.drawImage(myImage, 0, 0, 100, 100);
context.restore();
```

284

## Canvas Scaling Canvas Objects

```
transform(a, b, c, d, e, f);
```

- a: Horizontal scaling.
- b: Horizontal skewing.
- c: Vertical skewing.
- d: Vertical scaling.
- e: Horizontal moving.
- f: Vertical moving.

286

## Canvas Using Canvas Text

Property	Values	Note
font	CSS font string	Example: italic Arial, sans-serif
textAlign	start, end, left, right, center	Defaults to start
textBaseline	top, hanging, middle, alphabetic , ideographic, bottom	Defaults to alphabetic

```
// Draw title text on our canvas
context.save();
// The font will be 60 pixel, Impact face
context.font = "60px impact";
// Use a brown fill for our text
context.fillStyle = '#996600';
// Text can be aligned when displayed
context.textAlign = 'center';
// Draw the text in the middle of the canvas with a max
// width set to center properly
context.fillText('Happy Trails!', 200, 60, 400);
context.restore();
```

288

## Canvas Applying shadows

Property	Values	Note
shadowColor	Any	CSS color Can include an alpha component
shadowOffsetX	Pixel count	Positive values move shadow to the right, negative left
shadowOffsetY	Pixel count	Positive values move shadow down, negative up
shadowBlur	Gaussian blur	Higher values cause blurrier shadow edges

```
// Set some shadow on our text, black with 20% alpha
context.shadowColor = 'rgba(0, 0, 0, 0.2)';
// Move the shadow to the right 15 pixels, up 10
context.shadowOffsetX = 15;
context.shadowOffsetY = -10;
// Blur the shadow slightly
context.shadowBlur = 2;
```

289

## Canvas Events

- There are many different application possibilities for using the Canvas API:
  - graphs, charts, image editing, and so on.
- However, **one of the most intriguing uses for the canvas is to modify or overlay existing content.**
  - Areas on the map with high levels of activity are colored as hot (for example, red, yellow, or white).
  - Areas with less activity show no color change at all, or minimal blacks and grays.
- We are able to perform these uses because the Canvas object supports all the standard events
- See the example linked to this slide

290

<p><i>Università di Pisa</i></p>  <h2>Designing Web Applications</h2> <h3>css</h3> <p><b>Francesco Marcelloni</b> Department of Information Engineering University of Pisa ITALY</p>	<p><i>Francesco Marcelloni</i></p>	<p><i>Università di Pisa</i></p>	<p><i>Francesco Marcelloni</i></p> <h2>Cascading Style Sheets</h2> <ul style="list-style-type: none"> <li>■ Cascading Style Sheets (<b>CSS</b>) is the recommended way to control the presentation layer in a web document. The main advantage of CSS over presentational HTML markup is that the styling can be kept entirely separate from the content.</li> <li>■ For example, it is possible to store all the presentational styles for a 10,000-page web site in a single <b>CSS file</b>. CSS also provides far better control over presentation than do presentational element types in HTML.</li> </ul>
<p><i>Francesco Marcelloni</i></p>  <p>1</p> <h2>CSS Benefits</h2> <ul style="list-style-type: none"> <li>■ By externalizing the presentation layer, CSS offers a number of significant benefits: <ul style="list-style-type: none"> <li>■ All styling is kept in a limited number of style sheets. Editing one style sheet is obviously more efficient than editing 10,000 HTML files!</li> <li>■ The overall saving in bandwidth is measurable. <ul style="list-style-type: none"> <li>■ The style sheet is cached after the first request</li> <li>■ Removing all presentational markup from your web pages reduces their size and bandwidth usage — by more than 50% in many documented cases <ul style="list-style-type: none"> <li>■ Benefits for the site owner, through lower bandwidth and storage costs,</li> <li>■ Benefits for the site's visitors, for whom the web pages load faster.</li> </ul> </li> </ul> </li> </ul> </li></ul>	<p><i>Francesco Marcelloni</i></p>	<p><i>Università di Pisa</i></p>	<p><i>Francesco Marcelloni</i></p> <h2>CSS Benefits</h2> <ul style="list-style-type: none"> <li>■ The separation of content from presentation makes it easier for site owners to reuse the content for other purposes, such as RSS feeds or text-to-speech conversion.</li> <li>■ Separate styling rules can be used for different output media. We no longer need to create a special version of each page for printing <ul style="list-style-type: none"> <li>■ we can simply create a single style sheet that controls how every page on the site will be printed.</li> </ul> </li> <li>■ Although CSS is designed to be independent of the markup language of the documents to which it is applied, in reality, it is used mainly with <b>HTML</b> and <b>XML</b> (including <b>XHTML</b>).</li> </ul>
<p><i>Francesco Marcelloni</i></p>  <p>3</p> <h2>CSS Versions</h2> <ul style="list-style-type: none"> <li>■ The first CSS specification, <b>CSS1</b>, became a <b>World Wide Web Consortium (W3C)</b> recommendation in December 1996. <ul style="list-style-type: none"> <li>■ It included properties for controlling typography, such as fonts, text alignment, spacing, margins, and list formatting.</li> </ul> </li> <li>■ <b>CSS2</b> came out in 1998, and contained a lot of the features that designers had been longing for. <ul style="list-style-type: none"> <li>■ <b>Boxes</b> could be made to behave like HTML table cells, or they could be positioned in different ways;</li> <li>■ more powerful <b>selectors</b> were available;</li> <li>■ <b>style sheets</b> could be imported into other <b>style sheets</b>;</li> <li>■ style rules could be specific to certain output media; and so on.</li> <li>■ Vast improvements in the areas of paged media (printing), and the generation of content from the style sheet.</li> </ul> </li> </ul>	<p><i>Francesco Marcelloni</i></p>	<p><i>Università di Pisa</i></p>	<p><i>Francesco Marcelloni</i></p> <h2>CSS Versions</h2> <ul style="list-style-type: none"> <li>■ As it turned out, some parts of CSS2 were very difficult to implement, so the W3C decided to revise the specification and adapt it to real-world situations.</li> <li>■ The name of the revised version was "Cascading Style Sheets, Level 2 Revision 1"—<b>CSS2.1 for short</b>.</li> <li>■ In the last years, updates of different sections, called modules – <b>CSS3</b></li> </ul>

# Including Style Sheets in HTML Documents

## Inline Styles

- Place the rules in inline CSS specified in a style attribute of a markup tag
- The style attribute can contain any CSS property.

```
<p style="color:red; margin-left: 10%">This is a paragraph.</p>
```

- Use this method sparingly!**
  - Using style attributes creates a strong coupling between the content and the presentation, which is usually undesirable.
  - Inline CSS is more limited than internal or external style sheets. It is not possible to specify a media type, so style attributes will apply for all media types.

## Internal Style Sheet

- NOTE: Do not leave spaces between the property value and the units!**  
"margin-left:20 px" (instead of "margin-left:20px") will work in IE, but not in Firefox or Opera.

## To insert CSS into an HTML document

There are three ways of inserting a style sheet into an HTML document:

- Inline style
- Internal style sheet
- External style sheet

## Internal Style Sheet

- Place the rules within a separate, internal style sheet in the head section of an HTML page, **by using the <style> tag**
- An internal style sheet should be used when a single document has a unique style.

```
<head>
<style type="text/css"; media="screen">
<!--
  hr {color:red;}
  p {margin-left:20px;}
  body {background:red;}
-->
</style></head>
```

## External Style Sheet

- Place the rules in a separate, external style sheet that is referenced by a link element or an @import rule in a style element
- Ideal when the style is applied to several pages**
  - You can change the look of an entire Web site **by changing one file**.
  - An external style sheet can be written in any text editor.
  - The file should not contain any html tags.
  - Your style sheet should be saved with a .css extension.

## External Style Sheet

```
<head>
<title> CSS Example </title>
<link rel="stylesheet" type="text/css" href="ex1.css">
</head>
<body>
<h1>
  This header is 36 pt
</h1>
<h2>
  This header is blue
</h2>
<p>
  This paragraph has a left margin of 50 pixels
</p>
</body>
```

13

```
/*file ex1.css
body
{ background-color:yellow;}
h1
{ font-size:36pt; }
h2
{ color:blue; }
p
{ margin-left:50px; }
```

14

## Including External Style Sheet The Link Tag

### First Method: the Link Tag

- The `<link>` tag is the most used method to link to style sheets
- Note: The link element must be embedded in the head section, and it can appear any number of times.
- The attribute `rel` specifies the relationship between the current document and the linked document. When used in the style sheet inclusion `rel="stylesheet"`.
- The **attribute `type`** specifies the Multipurpose Internet Mail Extensions (MIME) type of the linked document

15

## Media Type

- Through style sheets you can specify how a **document is to be presented on different media**: on the screen, on paper, with a speech synthesizer, with a braille device, etc.
- Certain **CSS properties are only designed for certain media** (e.g., the 'page-break-before' property only applies to paged media). Style sheets for different media types may share a property, but require different values for that property.

17

## External Style Sheet

```
/*file ex1.css
body
{ background-color:yellow;}
h1
{ font-size:36pt; }
h2
{ color:blue; }
p
{ margin-left:50px; }
```

14

## Including External Style Sheet The @import at-rule

### Second Method: the directive @import

- The directive is used in the content of a style tag

```
<head>
<style type="text/css">
  @import url(/style.css);
</style>
</head>
```

16

## How can you specify the Media Type?

- There are currently **two ways to specify media dependencies for style sheets**:

1. **Specify the target medium from a style sheet with the @import at-rule:**

```
@import url("fancyfonts.css") screen;
```

or with the @media at-rules.

```
@media print {
  /* style sheet for print goes here */
}
```

18

## Media Type

2. Specify the target medium within the document language.

```
<head>
  <title> Link to a target medium </title>
  <link rel="stylesheet"
    type="text/css"
    media="print, handheld"
    href="foo.css">
</head>
<body>
  <p> The body... </p>
</body>
```

19

## Media Type

Media Type	Description
<b>all</b>	Used for all media type devices
<b>braille</b>	Used for braille tactile feedback devices
<b>embossed</b>	Used for paged braille printers
<b>handheld</b>	Used for small or handheld devices
<b>print</b>	Used for printers
<b>projection</b>	Used for projected presentations, like slides
<b>screen</b>	Used for computer screens
<b>speech</b>	Used for speech synthesizers
<b>tty</b>	Used for media using a fixed-pitch character grid, like teletypes and terminals
<b>tv</b>	Used for television-type devices

20

## Media Type

```
<head>
<style type="text/css" media="screen">
  h1 { background:black; color:white; text-align:center }
  h2 { color: red; font-style:italic }  h3 { display: none }
</style>
<style type="text/css" media="print">
  h1 { color: black; text-align: left } h2 { display: none }
</style>
<title>Example Media Type</title>
</head>
<body>
<h1>Example</h1>
<h2>This is not printed</h2>
<h3>This is not displayed</h3>
</body>
```

21

## Cascading Style Sheets: Syntax

## CSS style sheet

- A CSS style sheet consists of a list of **statements**. There are two kinds of statements:
  - at-rules**
  - rule sets**.
- There may be white space around the statements.
- Example
 

```
@import "subs.css";
@media print {
  @import "print-main.css";
  body { font-size: 10pt }
}
h1 {color: blue }
```

23

## CSS style sheet At-rule

### At-rules

- At-rules start with an **at-keyword**, an '@' character followed immediately by an identifier (for example, '@import', '@page').
- An at-rule consists of everything up to and including the next semicolon (;) or the next block, whichever comes first.
- A **block** starts with a left curly brace ({) and ends with the matching right curly brace (}).

24

## CSS style sheet Rule sets

- Rule sets

- A rule set (also called "rule") consists of a selector followed by a declaration block.
- A declaration block starts with a left curly brace ({} ) and ends with the matching right curly brace ({} ). In between there must be a list of zero or more semicolon-separated ( ; ) declarations.
- The selector consists of everything up to (but not including) the first left curly brace ({} ). A selector always goes together with a declaration block. When a user agent cannot parse the selector (i.e., it is not valid CSS 3.0), it must ignore the selector and the following declaration block (if any) as well.

25

## CSS style sheet Declarations

- Declarations

- A declaration is either empty or consists of a property name, followed by a colon (:), followed by a value. Around each of these there may be white space.

```
h1 { font-weight: bold }
h1 { font-size: 12px }
h1 { line-height: 14px }
h1 { font-family: Helvetica }
h1 { font-variant: normal }
h1 { font-style: normal }
```

=

```
h1 {
  font-weight: bold;
  font-size: 12px;
  line-height: 14px;
  font-family: Helvetica;
  font-variant: normal;
  font-style: normal
}
```

27

## CSS style sheet Comments

- Comments

- Begin with the characters "/\*" and end with the characters "\*/".
- May occur anywhere between tokens, and their contents have no influence on the rendering.
- May not be nested.

29

## CSS style sheet Rule set

- Rule sets (example)

```
h1, h2 {color: green }
h3, h4 & h5 {color: red }
h6 {color: black }
```

Since the "&" is not a valid token in a CSS 3.0 selector, a CSS 3.0 user agent must ignore the whole second line

26

## CSS style sheet Declarations

- Declarations

- A user agent must ignore a declaration with an invalid property name or an invalid value.

```
h1 { color: red; font-style: 12pt } /* Invalid value: 12pt */
p { color: blue; font-vendor: any; /* Invalid prop.: font-vendor */
   font-variant: small-caps }
em { font-style: normal }
```

The CSS parser will reduce the style sheet to  

```
h1 { color: red; }
p { color: blue; font-variant: small-caps }
em em { font-style: normal }
```

28

## CSS style sheet Selectors

- Pattern matching rules determine which style rules apply to elements in the document tree.

- These patterns, called **selectors**, may range from simple element names to rich contextual patterns.
- If all conditions in the pattern are true for a certain element, the selector matches the element.

- A **selector** is a chain of one or more simple selectors separated by combinator.
- A **simple selector** is either a type selector or universal selector followed immediately by zero or more attribute selectors, ID selectors, or pseudo-classes, in any order. The simple selector matches if all of its components match.
- **Combinators** are: white space, ">", and "+". White space may appear between a combinator and the simple selectors around it.

30

## Selectors Type Selector

### Type selector

- A type selector matches the name of a document language element type.
- ```
h1 { font-family: sans-serif }
p { text-align: justify }
div { position: absolute; left: 10px; top: 50px }
table { width: 80%; height: 50% }
```

31

## Selectors Universal Selector

### Universal selector

- The universal selector "\*" matches the name of any element type.
- ```
<head>
<style type="text/css">
  body { font-size: large; }
  h1 { color: green; }
  * { color: red; }
</style>
<title>Universal Selector</title>
</head>
<body>
  <h1> The heading is green </h1>
  <p> This text is red </p>
</body>
```

32

## Selectors Grouping

### Grouping

- When several selectors share the same declarations, they may be grouped into a comma-separated list.
- In this example, we condense three rules with identical declarations into one. Thus,

```
h1 { font-family: sans-serif }
h2 { font-family: sans-serif }
h3 { font-family: sans-serif }
```

is equivalent to:

```
h1, h2, h3 { font-family: sans-serif }
```

33

## Selectors Class Selectors

### Class Selectors

- If only type selectors were available, we would have that all the element instances would have the same format.
  - For instance:
- ```
p { font-family: Arial }
```
- To have different fonts for different paragraphs, we can exploit the class attribute.
  - We can assign style information to all elements with class= "myclass" as follows:
- ```
*.myclass { color: green } /* all elements with class=myclass */
.myclass { color: green } /* all elements with class=myclass */
```

34

## Selectors Class Selectors

- The following example assigns different font families to different paragraphs

```
<style type="text/css">
  .arial { font-family: Arial }
  .serif { font-family: serif }
</style>
<title> Font </title>
</head>
<body>
  <p>Paragraph</p>
  <p class="arial">This paragraph is in Arial font</p>
  <p class="serif">This paragraph is in Serif font</p>
</body>
```

35

## Selectors Multiple Classes

### Multiple classes

```
p.green.bold { color: green; font-weight: bold }
```

The rule matches any p element whose "class" attribute has been assigned a list of space-separated values that includes "green" and "bold"

<p class="green serif bold"> (OK)

<p class="serif bold"> (NO)

## Selectors Pseudo-Classes

- Pseudo-classes classify elements on characteristics other than their name, attributes or content; in principle characteristics that cannot be deduced from the document tree.
- Pseudo-classes may be dynamic, in the sense that an element may acquire or lose a pseudo-class while a user interacts with the document.
  - The exceptions are ':first-child', which can be deduced from the document tree, and ':lang()', which can be deduced from the document tree in some cases

43

## Selectors Pseudo-Classes

- The :link and :visited pseudo-classes
  - The :link pseudo-class applies for links that have not yet been visited.
  - The :visited pseudo-class applies once the link has been visited by the user.

```
a:link { color: blue; }
a:visited { color: fuchsia; text-decoration: none }
...
<a href ="pagina.html">Prova link</a>
```

45

## Selectors Pseudo-Classes

- The :target pseudo-class
  - URLs with an # followed by an anchor name link to a certain element within a document. The element being linked to is the target element.
  - The :target selector can be used to style the current active target element.

```
<style>
:target {
  border: 2px solid #D4D4D4;
  background-color: #e5eecc;
}
</style>
```

47

## Selectors Pseudo-Classes

- The :first-child pseudo-class matches an element that is the first child element of some other element.

```
<style type="text/css">
div > p:first-child { text-indent: 10pt } /*add indentation */
  </style>      /*for the first paragraph of a div */
</head>
<body>
<div class="note">
<p>The first P inside the note.</p>
<p>The second P inside the note.</p>
</div>
</body>
```

44

## Selectors Pseudo-Classes

- The :hover, :active, and :focus pseudo-classes
  - The :hover pseudo-class applies while the user designates an element (with some pointing device), but does not activate it.
    - A visual user agent could apply this pseudo-class when the cursor (mouse pointer) hovers over a box generated by the element (must be placed after the A:link and A:visited rules).
  - The :active pseudo-class applies while an element is being activated by the user.
    - For example, between the times the user presses the mouse button and releases it.
  - The :focus pseudo-class applies while an element has the focus (accepts keyboard events or other forms of text input).

```
a:hover { text-transform: uppercase }
a:active { color: red }
```

46

## Inheritance

- DOM tree (example)

48

## Summary of the selector syntax

Pattern	Meaning	Example
E	Matches any E element (i.e., an element of type E).	h1 { font-family: sans-serif; }
E F	Matches any F element that is a descendant of an E element.	h1 em { color: blue; } <h1>This headline is <em>very</em> important</h1>
E > F	Matches any F element that is a child of an element E.	div ol>li p { color: blue; }
E + F	Matches any F element immediately preceded by a sibling element E.	h1 + h2 { margin-top: -5mm; }
E[attrib]	Matches any E element with the "attrib" attribute set (whatever the value).	h1[title] { color: blue; }

49

## Summary of the selector syntax

Pattern	Meaning	Described in section	First defined in CSS level
*	any element	<a href="#">Universal selector</a>	2
E	an element of type E	<a href="#">Type selector</a>	1
E[foo]	an E element with a "foo" attribute	<a href="#">Attribute selectors</a>	2
E[foo="bar"]	an E element whose "foo" attribute value is exactly equal to "bar"	<a href="#">Attribute selectors</a>	2
E[foo~="bar"]	an E element whose "foo" attribute value is a list of whitespace-separated values, one of which is exactly equal to "bar"	<a href="#">Attribute selectors</a>	2
E[foo^="bar"]	an E element whose "foo" attribute value begins exactly with the string "bar"	<a href="#">Attribute selectors</a>	3
E[foo\$="bar"]	an E element whose "foo" attribute value ends exactly with the string "bar"	<a href="#">Attribute selectors</a>	3
E[foo*="bar"]	an E element whose "foo" attribute value contains the substring "bar"	<a href="#">Attribute selectors</a>	3
E[foo =“en”]	an E element whose "foo" attribute has a hyphen-separated list of values beginning (from the left) with "en"	<a href="#">Attribute selectors</a>	2

51

## Summary of the selector syntax

Pattern	Meaning	Described in section	First defined in CSS level
E:last-child	an E element, last child of its parent	<a href="#">Structural pseudo-classes</a>	3
E:first-of-type	an E element, first sibling of its type	<a href="#">Structural pseudo-classes</a>	3
E:last-of-type	an E element, last sibling of its type	<a href="#">Structural pseudo-classes</a>	3
E:only-child	an E element, only child of its parent	<a href="#">Structural pseudo-classes</a>	3
E:only-of-type	an E element, only sibling of its type	<a href="#">Structural pseudo-classes</a>	3

53

## Summary of the selector syntax

Pattern	Meaning	Example
E[attrib="value"]	Matches any E element whose "attrib" attribute value is exactly equal to "value".	span[class="example"] { color: blue; }
E[attrib~=“value”]	Matches any E element whose "attrib" attribute value is a list of space-separated values, one of which is exactly equal to "value".	a[rel~="copyright"] match the value "copyright copyleft copyeditor"
E[attrib="value"]	Matches any E element whose "attrib" attribute has a hyphen-separated list of values beginning (from the left) with "value".	*[lang="en"] { color : red }
E#myid	Matches any E element with ID equal to "myid".	h1#chapter1 { text-align: center }

50

## Summary of the selector syntax

Pattern	Meaning	Described in section	First defined in CSS level
E:root	an E element, root of the document	<a href="#">Structural pseudo-classes</a>	3
E:nth-child(n)	an E element, the n-th child of its parent	<a href="#">Structural pseudo-classes</a>	3
E:nth-last-child(n)	an E element, the n-th child of its parent, counting from the last one	<a href="#">Structural pseudo-classes</a>	3
E:nth-of-type(n)	an E element, the n-th sibling of its type	<a href="#">Structural pseudo-classes</a>	3
E:nth-last-of-type(n)	an E element, the n-th sibling of its type, counting from the last one	<a href="#">Structural pseudo-classes</a>	3
E:first-child	an E element, first child of its parent	<a href="#">Structural pseudo-classes</a>	2

52

## Summary of the selector syntax

Pattern	Meaning	Described in section	First defined in CSS level
E:empty	an E element that has no children (including text nodes)	<a href="#">Structural pseudo-classes</a>	3
E:link	an E element being the source anchor of a hyperlink of which the target is not yet visited (:link) or already visited (:visited)	<a href="#">The link pseudo-classes</a>	1
E:visited	an E element during certain user actions	<a href="#">The user action pseudo-classes</a>	1 and 2
E:active	an E element being the target of the referring URI	<a href="#">The target pseudo-class</a>	3
E:hover	an element of type E in language "fr" (the document language specifies how language is determined)	<a href="#">The :lang() pseudo-class</a>	2
E:focus	a user interface element E which is enabled or disabled	<a href="#">The UI element states pseudo-classes</a>	3
E:target			
E:lang(fr)			
E:enabled			
E:disabled			

54

## Summary of the selector syntax

Pattern	Meaning	Described in section	First defined in CSS level
E:checked	a user interface element E which is checked (for instance a radio-button or checkbox)	<a href="#">The UI element states pseudo-classes</a>	3
E::first-line	the first formatted line of an E element	<a href="#">The ::first-line pseudo-element</a>	1
E::first-letter	the first formatted letter of an E element	<a href="#">The ::first-letter pseudo-element</a>	1
E::before	generated content before an E element	<a href="#">The ::before pseudo-element</a>	2
E::after	generated content after an E element	<a href="#">The ::after pseudo-element</a>	2
E.warning	an E element whose class is "warning" (the document language specifies how class is determined).	<a href="#">Class selectors</a>	1

## Cascade, Specificity and Inheritance

### The Cascade Process of resolution

- For a given property, the user agent finds all declarations that apply to a specific element for the target media type
  - by analysing three sources
    - the user agent
    - the author
    - the user style sheets (customized set of styles to use by default which some user agent allows a user to create).

## Summary of the selector syntax

Pattern	Meaning	Described in section	First defined in CSS level
E#myid	an E element with ID equal to "myid".	<a href="#">ID selectors</a>	1
E:not(s)	an E element that does not match simple selector s	<a href="#">Negation pseudo-class</a>	3
E F	an F element descendant of an E element	<a href="#">Descendant combinator</a>	1
E > F	an F element child of an E element	<a href="#">Child combinator</a>	2
E + F	an F element immediately preceded by an E element	<a href="#">Adjacent sibling combinator</a>	2
E ~ F	an F element preceded by an E element	<a href="#">General sibling combinator</a>	3

## Cascade, specificity and inheritance

- The **Cascading term** indicates that style declarations cascade down to elements from many origins.
- The **cascade** computes a weight for each applicable declaration based on:
  - source order
  - importance
  - origin
  - specificity.
- This weight is used to determine exactly—and without conflict—which declaration should be applied to any given element.

### The Cascade Process of resolution

- Declarations are applied to the element, if
  - the associated selector matches the element **and**
  - the target medium matches the media list on all @media rules containing the declaration and on all links on the path through which the style sheet was reached.
- If there is more than one applicable declaration that sets a specific property, the cascade proceeds to step two.

## The Cascade Process of resolution

### 2. Sort the declarations according to their levels of importance, and origins.

- Declarations that are appended with the `!important` statement are called important declarations;
  - Otherwise they are called normal declarations.
- ```
p { font-size: 1em !important;}
```

61

## The Cascade Process of resolution

### 3. Sort declarations with the same level of importance and origin by selector specificity.

- The specificity of a selector is represented by four comma-separated values  $a, b, c, d$ , where the values in "a" are the most important and those in "d" are least important.

63

## The Cascade Process of resolution

### 4. Finally, if declarations have the same level of importance, origin, and specificity, sort them by the order in which they are specified; the last declaration wins.

- Note: If the link to the external style sheet is placed after the internal style sheet in HTML `<head>`, the external style sheet will override the internal style sheet!

65

## The Cascade Process of resolution

### 2. Sort the declarations according to their levels of importance, and origins.

- Declarations are sorted in the following ascending order:
  1. Transition declarations
  2. Important user agent declarations
  3. Important user declarations
  4. Important override declarations
  5. Important author declarations
  6. Animation declarations
  7. Normal override declarations
  8. Normal author declarations
  9. Normal user declarations
  10. Normal user agent declarations

62

## The Cascade Process of resolution

- A selector's specificity is calculated as follows:
  - $a = 1$  if the declaration is from a 'style' attribute rather than a rule with a selector (an inline style),  $a = 0$  otherwise.
  - $b = \text{number of ID attributes in the selector}$
  - $c = \text{number of other attributes and pseudo-classes in the selector}$
  - $d = \text{number of element names and pseudo-elements in the selector}$ .

64

## The Cascade Process of resolution

### Some examples

|                                 |                                    |
|---------------------------------|------------------------------------|
| <code>* {}</code>               | <code>/* a=0 b=0 c=0 d=0 */</code> |
| <code>li {}</code>              | <code>/* a=0 b=0 c=0 d=1 */</code> |
| <code>li:first-line {}</code>   | <code>/* a=0 b=0 c=0 d=2 */</code> |
| <code>ul li {}</code>           | <code>/* a=0 b=0 c=0 d=2 */</code> |
| <code>ul ol+li {}</code>        | <code>/* a=0 b=0 c=0 d=3 */</code> |
| <code>h1 + *[rel=up]{}{}</code> | <code>/* a=0 b=0 c=1 d=1 */</code> |
| <code>ul ol li.red {}</code>    | <code>/* a=0 b=0 c=1 d=3 */</code> |
| <code>li.red.level {}</code>    | <code>/* a=0 b=0 c=2 d=1 */</code> |
| <code>#x34y {}</code>           | <code>/* a=0 b=1 c=0 d=0 */</code> |
| <code>style=""</code>           | <code>/* a=1 b=0 c=0 d=0 */</code> |

66

## The Cascade Process of resolution

```
<style type="text/css">
    #redP { color: red }
    p.bluStyle {color:blue}
</style>
<title>Resolution Process</title>
</head>
<body>
<p id="redP" class="bluStyle" style="color: green"> Example 1 </p>
<p class="bluStyle"> Example 2 </p>
</body>
</html>
```

67

```
<head>
<style type="text/css">
body {
    color: #000;
    background-color: #fff;
}
#wrap {
    font-size: 2em;
    color: #333;
}
div {
    font-size: 1em;
}
```

68

## The Cascade Process of resolution

```
em {
    color: #666;
}
p.item {
    color: #fff;
    background-color: #ccc;
    border-style: dashed;
}
p {
    border: 1px solid black;
    padding: 0.5em;
}
</style>
</head>
```

69

```
<body>
<div id="wrap">
    <p>Normal Paragraph</p>
    <p class="item">
        This is the <em>cascade</em> in
        <a href="#">action</a>
    </p>
</div>
</body>
```

70

## Inheritance

- Inheritance is the process by which properties are passed from parent to child elements even though those properties have not been explicitly defined by other means.
- Inheritance is a mechanism that is separate from the cascade: inheritance applies to the DOM (Document Object Model) tree, while the cascade deals with the style sheet rules.**
- However, CSS properties set on an element via the cascade can be inherited by that element's child elements.

71

### DOM tree (example)

72

## Inheritance

```
<head>
<style type="text/css">
  body { color: red } h2 { color: black }
</style>
<title> Example </title>
</head>
<body>
  <h1>Heading (red)</h1>
  <p>
    Text of the <b>paragraph</b> (the colour is inherited)
  </p>
  <h2> The style of heading 2 is redefined </h2>
</body>
```

73

## Color Foreground color

- Foreground color: the 'color' property 'color'

**Value:** <color> | inherit

**Initial:** depends on user agent

**Applies to:** all elements

**Inherited:** yes

**Percentages:** N/A

**Media:** visual

**Computed value:** as specified

```
em { color: red } /* predefined color name */
em { color: rgb(255,0,0) } /* RGB range 0-255 */
```

75

## Color Foreground color

- **Hexadecimal notation:** a '#' immediately followed by either three or six hexadecimal characters.
  - The three-digit RGB notation (#rgb) is converted into six-digit form (#rrggbb) by replicating digits, not by adding zeros. This format allows defining 16777216 colors
- **Functional notation:** 'rgb(' followed by a comma-separated list of three numerical values (either three integer values or three percentage values) followed by ')'.
  - The integer value 255 corresponds to 100%, and to F or FF in the hexadecimal notation:  $\text{rgb}(255,255,255) = \text{rgb}(100\%,100\%,100\%) = \#FFF$ .
  - White space characters are allowed around the numerical values.

77

## Cascading Style Sheets: Properties

74

## Color Foreground color

- A <color> is either a keyword or a numerical RGB specification.

■ The list of color keywords is: aqua, black, blue, fuchsia, gray, green, lime, maroon, navy, olive, orange, purple, red, silver, teal, white, and yellow. These 17 colors have the following values

```
maroon #800000 red #ff0000 orange #ffa500 yellow #ffff00 olive #808000
purple #800080 fuchsia #ff00ff white #ffffff lime #00ff00 green #008000
navy #000080 blue #0000ff aqua #00ffff teal #008080
black #000000 silver #c0c0c0 gray #808080
```

76

## Color Foreground color

### Examples

```
body {color: black; background: white }
h1 { color: maroon }
h2 { color: olive }
em { color: #f00 } /* #rgb */
em { color: #ff0000 } /* #rrggbb */
em { color: rgb(255,0,0) }
em { color: rgb(100%, 0%, 0%) }
```

78

## Color Opacity

- The **opacity** property sets the opacity level for an element.
- The opacity-level describes the transparency-level, where 1 is not transparent at all, 0.5 is 50% see-through, and 0 is completely transparent.

```
<head>
<style>
div {
    background-color: red;
    opacity: 0.2;
}
</style>
</head>
```

79

## Color Background color

- 'background-color' (example)

```
<head>
<title> Background Color </title>
<style type="text/css">
body { background-color: #ccc }
#father { background-color: teal }
#son { background-color: red }
</style>
</head>
<body>
<div id="father"> Father element
    <div id="son"> Son Element </div>
</div>
</body>
```

81

## Background Image

- 'background-image' (example)

```
<head>
<title> Background Image </title>
<style type="text/css">
body { background-color: #ccc; background-image: url("tower.jpg") }
#father { background-color: teal; }
#son { background-color: red; }
</style>
</head>
<body>
<div id="father"> Father element
    <div id="son"> Son Element </div>
</div>
</body>
```

83

## Color Background color

- 'background-color'

**Value:** <color> | transparent | inherit  
**Initial:** transparent  
**Applies to:** all elements  
**Inherited:** no  
**Percentages:** N/A  
**Media:** visual

- This property sets the background color of an element.

```
h1 { background-color: #F00 }
```

80

## Background Image

- 'background-image'

**Value:** <uri> | none | inherit  
**Initial:** none  
**Applies to:** all elements  
**Inherited:** no  
**Percentages:** N/A  
**Media:** visual  
**Computed value:** absolute URI or none

- When setting a background image, authors should also specify a background color that will be used when the image is unavailable. When the image is available, it is rendered on top of the background color.

- By default, the image is repeated so it covers the entire element.

82

## Background Repeat

- 'background-repeat'

**Value:** repeat | repeat-x | repeat-y | no-repeat | space | round | inherit  
**Initial:** repeat  
**Applies to:** all elements  
**Inherited:** no  
**Percentages:** N/A  
**Media:** visual  
**Computed value:** as specified

- If a background image is specified, this property specifies whether the image is repeated (tiled), and how.

- By default, the background-image property repeats an image both horizontally and vertically

84

<p><i>Università di Pisa</i></p> <h2>Background Repeat</h2> <ul style="list-style-type: none"> <li>■ 'background-repeat'</li> <li>■ <b>repeat</b> The image is repeated both horizontally and vertically.</li> <li>■ <b>repeat-x</b> The image is repeated horizontally only.</li> <li>■ <b>repeat-y</b> The image is repeated vertically only.</li> <li>■ <b>no-repeat</b> The image is not repeated: only one copy of the image is drawn.</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Background Repeat</h2> <ul style="list-style-type: none"> <li>■ 'background-repeat'</li> <li>■ <b>space</b> The image is repeated as often as will fit within the background positioning area without being clipped and then the images are spaced out to fill the area.</li> <li>■ <b>round</b> The image is repeated as often as will fit within the background positioning area. If it doesn't fit a whole number of times, it is rescaled so that it does.</li> </ul>	<p><i>Francesco Marcelleni</i></p>

## Background Position

### 'background-position'

- **<percentage>** A percentage X aligns the point X% across (for horizontal) or down (for vertical) the image with the point X% across (for horizontal) or down (for vertical) the element's padding box.

For example, with a value pair of '75% 50%', the point 75% across and 50% down the image is to be placed at the point 75% across and 50% down the padding box.

## Background Position

### 'background-position'

- **<length>** A length L aligns the top left corner of the image a distance L to the right of (for horizontal) or below (for vertical) the top left corner of the element's padding box.

For example, with a value pair of '2cm 1cm', the upper left corner of the image is placed 2cm to the right and 1cm below the upper left corner of the padding box.

## Measurement units

### Relative units

- **em**: the 'font-size' of the relevant font (preferred)
- **ex**: the 'x-height' of the relevant font

### Absolute units

- **in**: inches — 1 inch is equal to 2.54 centimeters.
- **cm**: centimeters
- **mm**: millimeters
- **pt**: points — the points used by CSS 2.1 are equal to 1/72nd of an inch.
- **pc**: picas — 1 pica is equal to 12 points.
- **px**: pixels — 1/96 inch

## Relative Length

## Background Position

### 'background-position'

#### top

Equivalent to '0%' for the vertical position.

#### right

Equivalent to '100%' for the horizontal position.

#### bottom

Equivalent to '100%' for the vertical position.

#### left

Equivalent to '0%' for the horizontal position.

#### center

Equivalent to '50%' for the horizontal position if it is not otherwise given, or '50%' for the vertical position if it is.

## Text format White Space

### ■ 'white-space'

**Value:** normal | pre | nowrap | pre-wrap | pre-line | inherit  
**Initial:** normal  
**Applies to:** all elements  
**Inherited:** yes  
**Percentages:** N/A  
**Media:** visual  
**Computed value:** as specified

- This property declares how white space inside the element is handled.

115

## Text format White Space

### ■ 'white-space' (example)

```
<style type="text/css">
  #first { white-space: pre; font-size:xx-large; }
  #second { white-space: nowrap; font-size:xx-large; }
  #third { white-space: pre-wrap; font-size:xx-large; }
  #fourth { white-space: pre-line; font-size:xx-large; }
</style>

<!--
  Here, the spaces      are collapsed</p>
<p id="first">Here, the spaces      are not collapsed</p>
<p id="second">Here, the spaces...    </p>
<p id="third">Here, the spaces ...   </p>
<p id="fourth">Here, the spaces ...  </p>
</body>
```

117

## Character Style Font Family

### ■ 'font-family'

- <generic family> - a group of font families with a similar look (like "Serif" or "Monospace")
- <font family> - a specific font family (like "Times New Roman" or "Arial")

Generic family	Font family	Description
Serif	Times New Roman Georgia	Serif fonts have small lines at the ends on some characters
Sans-serif	Arial Verdana	"Sans" means without - these fonts do not have the lines at the ends of characters
Monospace	Courier New Lucida Console	All monospace characters has the same width

119

## Text format White Space

### ■ 'white-space'

- normal** - This value directs user agents to collapse sequences of white space, and break lines as necessary to fill line boxes.
- pre** - This value prevents user agents from collapsing sequences of white space. Lines are only broken at newlines in the source.
- nowrap** - This value collapses white space as for 'normal', but suppresses line breaks within text.
- pre-wrap** - This value prevents user agents from collapsing sequences of white space. Lines are broken at newlines in the source as necessary to fill line boxes (not in Explorer).
- pre-line** - This value directs user agents to collapse sequences of white space. Lines are broken at newlines in the source as necessary to fill line boxes.

116

## Character Style Font Family

### ■ 'font-family'

**Value:** [[ <family-name> | <generic-family> ] [, <family-name>| <generic-family>]\* ] | inherit

**Initial:** depends on user agent

**Applies to:** all elements

**Inherited:** yes

**Percentages:** N/A

**Media:** visual

**Computed value:** as specified

- This property allows choosing the family font.

118

## Character Style Font Family

### ■ 'font-family'

The font-family property should hold several font names as a "fallback" system. If the browser does not support the first font, it tries the next font

- Start with the font you want, and end with a generic family, to let the browser pick a similar font in the generic family, if no other fonts are available.

**Serif fonts** (stroke endings have ornaments)

p {font-family:"Times New Roman", Times, serif;}

**Sans-Serif fonts** (stroke endings are plain)

p {font-family:Arial, Helvetica, sans-serif;}

**Monospace Fonts** (characters have the same fixed width)

p {font-family:"Courier New", Courier, monospace;}

120

The values '100' to '900' form an ordered sequence, where each number indicates a weight that is at least as dark as its predecessor.</li> </ul> <p>125</p> <p><i>IN SUPREME DIGNITATI</i></p>	<p><i>Francesco Marcelleni</i></p> <h2>Character Style Font Weight</h2> <ul style="list-style-type: none"> <li>■ 'font-weight'</li> </ul> <ul style="list-style-type: none"> <li>■ 'normal' is synonymous with '400'</li> <li>■ 'bold' is synonymous with '700'</li> <li>■ 'bolder' selects the next weight that is assigned to a font that is darker than the inherited one.</li> <li>■ 'lighter' selects the next lighter keyword with a different font from the inherited one.</li> </ul> <ul style="list-style-type: none"> <li>■ There is no guarantee that there will be a darker face for each of the 'font-weight' values; for example, some fonts may have only a normal and a bold face, while others may have eight face weights. There is no guarantee on how a UA will map font faces within a family to weight values.</li> </ul> <p>126</p> <p><i>IN SUPREME DIGNITATI</i></p>

## Character Style Font Weight

### 'font-weight' (example)

```
<head>
  <title> Text format </title>
<style type="text/css">
  div { font-weight: normal; border: thin solid red}
  div * {font-weight: bolder}
</style>
</head>
<body>
  <p> Normal </p>
  <div> Normal
    <p> slightly bolder </p>
  </div>
</body>
```

127

## Character Style Line Height

### 'line-height'

**Value:** normal | <number> | <length> | <percentage> | inherit  
**Initial:** normal  
**Applies to:** all elements  
**Inherited:** yes  
**Percentages:** refer to the font size of the element itself  
**Media:** visual  
**Computed value:** for <length> and <percentage> the absolute value; otherwise as specified

Specifies the minimal height between two text lines (in particular, between the baselines, without considering the letters such 'g' and 'q').

129

## Character Style Line Height

### 'line-height' (example)

```
...
<style type="text/css">
  div { width: 200px; border: thin solid; margin: 30px}
  .par1 { font-size: 12pt; line-height: 250% }
  .par2 { font-size: 12pt; line-height: 0.6 }
</style>
</head>
<body>
<div>Normal flkmgnlkg sgksklgnzng lsgdknsdklgnsdgs</div>
<div class="par1">New interline fddgdfghjkjhkhjk
thgfhfghfghfghgfh </div>
<div class="par2"> New interline gdggfdggdfg ddfgdfghseuh
hherhhtrhdf </div> </body>
```

131

## Character Style Font Variant

### 'font-variant'

**Value:** normal | small-caps | inherit  
**Initial:** normal  
**Applies to:** all elements  
**Inherited:** yes  
**Percentages:** N/A  
**Media:** visual  
**Computed value:** as specified

In a small-caps font the lower case letters look similar to the uppercase ones, but in a smaller size and with slightly different proportions.

128

## Character Style Line Height

### 'line-height'

- **<length>** The specified length is used in the calculation of the line box height. Negative values are illegal.
- **<number>** The used value of the property is this number multiplied by the element's font size. Negative values are illegal. The computed value is the same as the specified value.
- **<percentage>** The computed value of the property is this percentage multiplied by the element's computed font size. Negative values are illegal.

130

## Character Style Font

### 'font'

**Value:** [ [ <font-style> ] || <font-variant> ] || <font-weight> ]?<font-size> [ / <line-height> ]? <font-family> | caption | icon | menu | message-box | small-caption | status-bar | inherit

**Initial:** see individual properties

**Applies to:** all elements

**Inherited:** yes

**Percentages:** see individual properties

**Media:** visual

**Computed value:** see individual properties

```
p { font: bold italic large Palatino, serif }
```

132

## Character Style Font

### 'font'

- **caption** - The font used for captioned controls (e.g., buttons, drop-downs, etc.).
- **icon** - The font used to label icons.
- **menu** - The font used in menus (e.g., dropdown menus and menu lists).
- **message-box** - The font used in dialog boxes.
- **small-caption** - The font used for labeling small controls.
- **status-bar** - The font used in window status bars.

```
button p { font: menu }
```

## Block and Inline Elements

- A **block element** is an element that takes up the full width available, and has a line break before and after it.
- Examples of block elements:
 

```
<h1>
<p>
<div>
```
- An **inline element** only takes up as much width as necessary, and does not force line breaks.
- Examples of inline elements:
 

```
<span>
<a>
```

## Box Model

- **Margin** - does not have a background color, and it is completely transparent
- **Border** - is affected by the background color of the box
- **Padding** - is affected by the background color of the box
- **Content** - The content of the box, where text and images appear

**Note:** When you specify the width and height properties of an element with CSS, **you are just setting the width and height of the content area.**

**Total element width** = width + left padding + right padding + left border + right border + left margin + right margin

**Total element height** = height + top padding + bottom padding + top border + bottom border + top margin + bottom margin

## Box Model

## Box Model

- All HTML elements can be considered as boxes. In CSS, the term "box model" is used when talking about design and layout.
- The CSS box model is essentially a box that wraps around HTML elements, and it consists of: margins, borders, padding, and the actual content.

## Box Model Example

```
<head>
  <title> Text format </title>
<style type="text/css">
  div
    { width:220px; padding:10px; border:5px solid gray; margin:30px
      10px; }
  </style>
</head>
<body>
  <div>This is a box. Total width = 270px </div>
  <div>This is a box. Total width = 270px </div>
</body>
```

<p><i>Università di Pisa</i></p> <h2>Box Model Padding</h2> <ul style="list-style-type: none"> <li>▪ 'padding-top', 'padding-right', 'padding-bottom', 'padding-left'           <ul style="list-style-type: none"> <li><b>Value:</b> &lt;padding-width&gt;   inherit</li> <li><b>Initial:</b> 0</li> <li><b>Applies to:</b> all elements except table-row-group, table-header-group, table-footer-group, table-row, table-column-group and table-column</li> <li><b>Inherited:</b> no</li> <li><b>Percentages:</b> refer to width of containing block</li> <li><b>Media:</b> visual</li> <li><b>Computed value:</b> the percentage as specified or the absolute length</li> </ul> </li> <li>▪ Values for padding cannot be negative</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p>  <h2>Box Model Padding</h2> <ul style="list-style-type: none"> <li>▪ 'padding-top', 'padding-right', 'padding-bottom', 'padding-left'           <ul style="list-style-type: none"> <li>&lt;padding-width&gt;</li> <li>▪ &lt;length&gt; Specifies a fixed width.</li> <li>▪ &lt;percentage&gt; The percentage is calculated with respect to the width of the generated box's containing block, even for 'padding-top' and 'padding-bottom'.</li> </ul> </li> </ul>	<p><i>Francesco Marcelleni</i></p>

<p><i>Università di Pisa</i></p>  <h2>Box Model Border Width</h2> <pre>&lt;style type="text/css"&gt;   ul { padding: 3px 3px 3px 3px }   li.pad30 {padding: 30px 30px 30px 30px}   li.pad60 {padding: 60px 60px 60px 60px} &lt;/style&gt;&lt;/head&gt; &lt;body&gt;&lt;ul&gt;   &lt;li&gt;First element of list&lt;/li&gt;   &lt;li class="pad30"&gt;Second element with padding 30&lt;/li&gt;   &lt;li class="pad60"&gt;Second element with padding 60&lt;/li&gt; &lt;/ul&gt;&lt;/body&gt;</pre>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p>  <h2>Box Model Border Width</h2> <ul style="list-style-type: none"> <li>▪ 'border-top-width', 'border-right-width', 'border-bottom-width', 'border-left-width'</li> <li><b>Value:</b> &lt;border-width&gt;   inherit</li> <li><b>Initial:</b> medium</li> <li><b>Applies to:</b> all elements</li> <li><b>Inherited:</b> no</li> <li><b>Percentages:</b> N/A</li> <li><b>Media:</b> visual</li> <li><b>Computed value:</b> absolute length; '0' if the border style is 'none' or 'hidden'</li> <li>▪ These properties set the width of the top, right, bottom, and left border of a box.</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p>  <h2>Box Model Border Width</h2>

## Box Model Border Width

- 'border-top-width', 'border-right-width', 'border-bottom-width', 'border-left-width'
  - <border-width>
    - thin - a thin border.
    - medium - a medium border.
    - thick - a thick border.
    - <length> - the border's thickness has an explicit value.  
Explicit border widths cannot be negative.

The interpretation of the first three values depends on the user agent. The following relationships must hold, however:  
'thin' <='medium' <= 'thick'.

145

## Box Model Border Width

- 'border-width'
  - Value:** <border-width>{1,4} | inherit
  - Initial:** see individual properties
  - Applies to:** all elements
  - Inherited:** no
  - Percentages:** N/A
  - Media:** visual
  - Computed value:** see individual properties

- This property is a shorthand property for setting 'border-top-width', 'border-right-width', 'border-bottom-width', and 'border-left-width' at the same place in the style sheet.

146

## Box Model Border Width

- 'border-width'
  - If there is only **one value**, it applies to all sides.
  - If there are **two values**, the top and bottom borders are set to the first value and the right and left are set to the second.
  - If there are **three values**, the top is set to the first value, the left and right are set to the second, and the bottom is set to the third.
  - If there are **four values**, they apply to the top, right, bottom, and left, respectively.

```
h1 { border-width: thin }           /* thin thin thin thin */
h1 { border-width: thin thick }     /* thin thick thin thick */
```

147

## Box Model Border Color

- 'border-color'
  - Value:** [ <color> | transparent ]{1,4} | inherit
  - Initial:** see individual properties
  - Applies to:** all elements
  - Inherited:** no
  - Percentages:** N/A
  - Media:** visual
  - Computed value:** see individual properties

- The 'border-color' property can have from one to four values, and the values are set on the different sides as for 'border-width'.

```
div {border-color: red yellow blue green}
```

149

## Box Model Border Color

- 'border-top-color', 'border-right-color', 'border-bottom-color', 'border-left-color'
  - Value:** <color> | transparent | inherit
  - Initial:** the value of the 'color' property
  - Applies to:** all elements
  - Inherited:** no
  - Percentages:** N/A
  - Media:** visual
  - Computed value:** when taken from the 'color' property, the computed value of 'color'; otherwise, as specified

- <color> - Specifies a color value.
- transparent - The border is transparent (though it may have width).

148

## Box Model Border Style

- 'border-top-style', 'border-right-style', 'border-bottom-style', 'border-left-style'
  - Value:** <border-style> | inherit
  - Initial:** none
  - Applies to:** all elements
  - Inherited:** no
  - Percentages:** N/A
  - Media:** visual
  - Computed value:** as specified

- The border style properties specify the line style of a box's border (solid, double, dashed, etc.).

150

## Box Model Border Style

- 'border-top-style', 'border-right-style', 'border-bottom-style', 'border-left-style'
- <border-style>
- none - no border; the computed border width is zero.
  - hidden - same as 'none', except in terms of border conflict resolution for table elements.
  - dotted - the border is a series of dots.
  - dashed - the border is a series of short line segments.
  - solid - the border is a single line segment.
  - double - the border is two solid lines. The sum of the two lines and the space between them equals the value of 'border-width'.
  - groove - the border looks as though it were carved into the canvas.

151

## Box Model Border Style

none

groove

dotted

ridge

dashed

inset

solid

outset

double

153

## Box Model Border Style

```
<style type="text/css">
  div { border-style: inset; border-width: thick;
        border-color: red; }
  li {border-color: blue}
  li.bor1 {border-style: groove; border-width:
            medium medium medium medium}
  li.bor2 {border-style: ridge; border-width:
            thin thin thin thin}
</style>
</head>
```

155

## Box Model Border Style

- 'border-top-style', 'border-right-style', 'border-bottom-style', 'border-left-style'

&lt;border-style&gt; (continued)

- ridge - the opposite of 'groove': the border looks as though it were coming out of the canvas.
- inset - the border makes the box look as though it were embedded in the canvas.
- outset - the opposite of 'inset': the border makes the box look as though it were coming out of the canvas.

152

## Box Model Border Style

- 'border-style'

**Value:** <border-style>{1,4} | inherit**Initial:** see individual properties**Applies to:** all elements**Inherited:** no**Percentages:** N/A**Media:** visual**Computed value:** see individual properties

- The 'border-style' property **sets the style of the four borders**. It can have from one to four values, and the values are set on the different sides as for 'border-width' above.

#xy34 { border-style: solid dotted }

154

## Box Model Border Style

```
<body>
  <div>
    <ul>
      <li>Element without specific border</li>
      <li class="bor1">Element with groove border</li>
      <li>Element without specific border</li>
      <li class="bor2">Element with ridge border</li>
    </ul>
  </div>
</body>
```

156

<p><i>Università di Pisa</i></p> <h2>Box Model Border</h2> <ul style="list-style-type: none"> <li>■ 'border-top', 'border-right', 'border-bottom', 'border-left'</li> </ul> <p><b>Value:</b> [ &lt;border-width&gt;    &lt;border-style&gt;    &lt;'border-top-color'&gt; ]   inherit  <b>Initial:</b> see individual properties  <b>Applies to:</b> all elements  <b>Inherited:</b> no  <b>Percentages:</b> N/A  <b>Media:</b> visual  <b>Computed value:</b> see individual properties</p>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Box Model Border radius</h2> <ul style="list-style-type: none"> <li>■ border-top-left-radius, border-top-right-radius, border-bottom-right-radius, border-bottom-left-radius</li> </ul> <p><b>Value:</b> [ &lt;length&gt;    &lt;percentage&gt; ]   inherit  <b>Initial:</b> 0  <b>Applies to:</b> all elements  <b>Inherited:</b> no  <b>Percentages:</b> Refer to corresponding dim. of the border box  <b>Media:</b> visual  <b>Computed value:</b> two absolute &lt;length&gt; or percentages</p>
<p>157</p>  <p>This is a shorthand property for setting the width, style, and color of the top, right, bottom, and left border of a box.</p> <pre>h1 { border-bottom: thick solid red }</pre>	<p>158</p> 
<p><i>Università di Pisa</i></p> <h2>Box Model Border radius</h2> <ul style="list-style-type: none"> <li>■ The two length or percentage values of the 'border-*-radius' properties define the radii of a quarter ellipse that defines the shape of the corner of the outer border edge (see the diagram below). The first value is the horizontal radius, the second the vertical radius.</li> </ul> 	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Box Model Border radius</h2> <p>Example:</p> <pre>div {   border: 2px solid #a1a1a1;   padding: 10px 40px;   background: #dddddd;   width: 300px;   border-radius: 25px; }</pre>
<p>159</p>  <p>159</p>  <p>The two length or percentage values of the 'border-*-radius' properties define the radii of a quarter ellipse that defines the shape of the corner of the outer border edge (see the diagram below). The first value is the horizontal radius, the second the vertical radius.</p> 	<p>160</p>  <p>160</p>  <p>Example:</p> <pre>&lt;style&gt; div {   background-color: lightgrey;   border: 30px solid transparent;   border-image: url('border.png');   border-image-slice: 30;   border-image-repeat: repeat; } &lt;/style&gt;</pre> 

## Box Model Box shadow

- **Box-shadow**

**Value:** none | <shadow> [ , <shadow> ]\*

**Initial:** none

**Applies to:** all elements

**Inherited:** no

**Percentages:** N/A

**Media:** visual

**Computed value:** any <length> made absolute; any specified color computed; otherwise as specified

<shadow> = inset? && <length>{2,4} && <color>?

The 'box-shadow' property attaches one or more drop-shadows to the box.

163

## Box Model Box shadow

```
border:5px solid blue;
background-color:orange;
width: 144px;
height: 144px;
```

```
border-radius: 20px; border-radius: 0;
```

```
box-shadow:
  rgba(0,0,0,0.4)
  10px 10px;
```

```
box-shadow:
  rgba(0,0,0,0.4)
  10px 10px
  inset
```

165

## Box Model Margin

- **'margin-top', 'margin-bottom', 'margin-right', 'margin-left'**

**Value:** <margin-width> | inherit

**Initial:** 0

**Applies to:** all elements except elements with table display types other than table-caption, table and inline-table

**Inherited:** no

**Percentages:** refer to width of containing block

**Media:** visual

**Computed value:** the percentage as specified or the absolute length

- These properties **set the top, right, bottom, and left margin of a box.**

```
h1 { margin-top: 2em }
```

167

## Box Model Box shadow

- **1st <length>**

Specifies the horizontal offset of the shadow. A positive value draws a shadow that is offset to the right of the box, a negative length to the left.

- **2nd <length>**

Specifies the vertical offset of the shadow. A positive value offsets the shadow down, a negative one up.

- **3rd <length>**

Specifies the blur radius. Negative values are not allowed. If the blur value is zero, the shadow's edge is sharp. Otherwise, the larger the value, the more the shadow's edge is blurred.

- **4th <length>**

Specifies the spread distance. Positive values cause the shadow to expand in all directions by the specified radius. Negative values cause the shadow to contract.

164

## Box Model Box shadow

```
border:5px solid blue;
background-color:orange;
width: 144px;
height: 144px;
```

```
border-radius: 20px; border-radius: 0;
```

```
box-shadow:
  rgba(0,0,0,0.4)
  10px 10px 0
  10px /* spread */
```

```
box-shadow:
  rgba(0,0,0,0.4)
  10px 10px 0
  10px /* spread */
  inset
```

166

## Box Model Margin

- **'margin-top', 'margin-bottom', 'margin-right', 'margin-left'**

<margin-width>

- **<length>** - specifies a fixed width.

- **<percentage>** - the percentage is calculated with respect to the width of the generated box's containing block.

- **auto** – the margins are automatically computed based on the values of width, height, padding and borders in such a way that all the spaces in the box is occupied.

- Note: adjoining margins (no non-empty content, padding or border areas) of two or more boxes (which may be next to one another or nested) combine to form a single margin corresponding to the maximum value (**collapsing margins**).

168

<p><i>Università di Pisa</i></p> <h2>Box Model Margin</h2> <ul style="list-style-type: none"> <li>■ 'margin'       <p><b>Value:</b> &lt;margin-width&gt;{1,4}   inherit</p> <p><b>Initial:</b> see individual properties</p> <p><b>Applies to:</b> all elements except elements with table display types other than table-caption, table and inline-table</p> <p><b>Inherited:</b> no</p> <p><b>Percentages:</b> refer to width of containing block</p> <p><b>Media:</b> visual</p> <p><b>Computed value:</b> see individual properties</p> </li> <li>■ The 'margin' property is a shorthand property for setting 'margin-top', 'margin-right', 'margin-bottom', and 'margin-left' at the same place in the style sheet.</li> </ul>	<p><i>Università di Pisa</i></p> <h2>Box Model Margin</h2> <ul style="list-style-type: none"> <li>■ 'margin'       <ul style="list-style-type: none"> <li>If there is only <b>one value</b>, it applies to all sides.</li> <li>If there are <b>two values</b>, the top and bottom margins are set to the first value and the right and left margins are set to the second.</li> <li>If there are <b>three values</b>, the top is set to the first value, the left and right are set to the second, and the bottom is set to the third.</li> <li>If there are <b>four values</b>, they apply to the top, right, bottom, and left, respectively.</li> </ul> </li> </ul>

## Box Model Width and Height (Example)

- 'width' and 'height' (example)

```
li {
    ...
    height: 200px
}

li.withborder {
    ...
    height: 100px
}
```

175

## Box Model Positioning

- A box may be laid out according to three positioning schemes:

- **Normal flow.** Normal flow includes block formatting of block boxes, inline formatting of inline boxes, relative positioning of block or inline boxes, and positioning of run-in boxes.
- **Floats.** In the float model, a box is first laid out according to the normal flow, then taken out of the flow and shifted to the left or right as far as possible. Content may flow along the side of a float.
- **Absolute positioning.** In the absolute positioning model, a box is removed from the normal flow entirely (it has no impact on later siblings) and assigned a position with respect to a containing block.

176

## Box Model Positioning

- The 'position' and 'float' properties determine which of the positioning algorithms is used to calculate the position of a box.

- **'position'**

**Value:** static | relative | absolute | fixed | inherit  
**Initial:** static  
**Applies to:** all elements  
**Inherited:** no  
**Percentages:** N/A  
**Media:** visual  
**Computed value:** as specified

177

## Box Model Positioning

- **'position'**

- **relative**

The box's position is calculated according to the normal flow (this is called the position in normal flow). Then the box is offset relative to its normal position.

When a box B is relatively positioned, the position of the following box is calculated as though B were not offset.

```
<style type="text/css">
img {position: relative; left: 400px; top: 200px}
</style>
```

179

## Box Model Positioning

- 'position'

- **static**

The box is laid out according to the normal flow. The 'top', 'right', 'bottom', and 'left' properties do not apply.

```
<head>
```

```
<title>Examples of positioning </title>
```

```
<style type="text/css">
```

```
img {position: static;}
```

```
</style>
```

```
</head>
```

```
<body>
```

```
<p>Example of image positioning </p>
```

```
<p>  </p>
```

```
<p>Example of image positioning</p>
```

```
</body>
```

178

## Box Model Positioning

- **'position'**

- **absolute**

The box's position (and possibly size) is specified with the 'top', 'right', 'bottom', and 'left' properties. These properties specify offsets with respect to the first block containing the box in which a positioning is defined. **Absolutely positioned boxes are taken out of the normal flow.** This means they have no impact on the layout of later siblings. Also, though absolutely positioned boxes have margins, they do not collapse with any other margins.

```
<style type="text/css">
```

```
img {position: absolute; left: 400px; top: 200px}
```

```
</style>
```

180

<p>Università di Pisa</p>  <h2>Box Model Positioning</h2> <ul style="list-style-type: none"> <li>■ 'position'</li> <li>■ fixed           <ul style="list-style-type: none"> <li>The position is calculated according to the 'absolute' model, but the box is fixed with respect to some reference.               <ul style="list-style-type: none"> <li>▪ The margins do not collapse with any other margins.</li> <li>▪ In the case of <b>handheld, projection, screen, tty, and tv media types</b>, the box is fixed with respect to the viewport and does not move when scrolled.</li> <li>▪ In the case of the <b>print media type</b>, the box is rendered on every page, and is fixed with respect to the page box, even if the page is seen through a viewport (in the case of a print-preview, for example).</li> <li>▪ For other media types, the presentation is undefined.</li> </ul> </li> </ul> <p>Note: fixed does not work in Explorer</p> </li></ul>	<p>Francesco Marcelleni</p>  <h2>Box Model Positioning</h2>	<p>Università di Pisa</p>  <h2>Box Model Positioning</h2>

<p>183</p> <p>Università di Pisa</p>  <h2>Box Model Positioning – z-index</h2> <ul style="list-style-type: none"> <li>■ 'z-index'</li> <li>■ &lt;integer&gt; - This integer is the stack level of the generated box in the current stacking context. The box also establishes a local stacking context in which its stack level is '0'.           <ul style="list-style-type: none"> <li>▪ Auto - The stack level is the same as its parent's box. The box does not establish a new local stacking context.</li> </ul> </li> </ul> <p>Each box has an integer stack level, which is its position on the z-axis relative to other boxes in the same stacking context.</p> <ul style="list-style-type: none"> <li>■ Boxes with greater stack levels are always formatted in front of boxes with lower stack levels.</li> <li>■ Boxes may have negative stack levels.</li> <li>■ Boxes with the same stack level in a stacking context are stacked back-to-front according to document tree order.</li> </ul>	<p>Francesco Marcelleni</p>  <h2>Box Model Positioning – z-index</h2> <ul style="list-style-type: none"> <li>■ 'z-index' (example)</li> </ul> <pre>&lt;head&gt; &lt;style type="text/css"&gt; #father1 { position: absolute; left: 10px; top: 10px; width: 300px; height: 200px; background-color: yellow; z-index: 3;} #father2 { position: absolute; left: 50px; top: 50px; width: 300px; height: 200px; background-color: red; z-index: 2;} #son1 { position: absolute; z-index: 1} #son2 { position: absolute; z-index: 4} &lt;/style&gt; &lt;/head&gt;</pre>	<p>Università di Pisa</p>  <h2>Box Model Positioning – z-index</h2>

## Box Model Positioning – z-index

- 'z-index' (example) (continued)

```
<body>
<div id="father1"> Father 1
<p id="son1"> Son 1 </p>
</div>
<div id="father2"> Father 2
<p id="son2"> Son 2 </p>
</div>
</body>
```

187

## Box Model Float

- 'float'

- left

The element generates a block box that is floated to the left. Content flows on the right side of the box, starting at the top (subject to the 'clear' property).

- right

Similar to 'left', except the box is floated to the right, and content flows on the left side of the box, starting at the top.

- none

The box is not floated.

The element has to have an explicit width

189

## Box Model Clear

- 'clear'

**Value:** none | left | right | both | inherit  
**Initial:** none  
**Applies to:** block-level elements  
**Inherited:** no  
**Percentages:** N/A  
**Media:** visual

This property indicates which sides of an element's box(es) may not be adjacent to an earlier floating box. The 'clear' property does not consider floats inside the element itself or in other block formatting contexts.

191

## Box Model Float

- 'float'

**Value:** left | right | none | inherit

**Initial:** none

**Applies to:** all, but positioned elements

**Inherited:** no

**Percentages:** N/A

**Media:** visual

■ This property specifies whether a box should float to the left, right, or not at all. It may be set for any element, but only applies to elements that generate boxes that are not absolutely positioned.

■ Elements are floated horizontally, this means that an element can only be floated left or right, not up or down.

188

## Box Model Float

- 'float' (example)

```
<style type="text/css">
img { float: none } /* could be also omitted*/
</style>
</head>
<body>
<p> float: none </p>
<p></p>
<p> The text follows the normal flow </p>
</body>
```

img { float: left }

img { float: right }

190

## Box Model Clear

- 'clear'

**left** - place the top border edge below the bottom outer edge of any left-floating boxes that resulted from elements earlier in the source document.

**right** - place the top border edge below the bottom outer edge of any right-floating boxes that resulted from elements earlier in the source document.

**both** - place the top border edge below the bottom outer edge of any right-floating and left-floating boxes that resulted from elements earlier in the source document.

**none** - no constraint on the box's position with respect to floats.

192

<p><i>Università di Pisa</i></p>  <h2>Box Model Clear</h2> <ul style="list-style-type: none"> <li>■ 'clear' (example)           <pre>&lt;head&gt;             &lt;title&gt; Examples of positioning &lt;/title&gt; &lt;style type="text/css"&gt;   img { float: right }   p { clear: right } &lt;/style&gt; &lt;/head&gt; &lt;body&gt;   &lt;p&gt; float: none &lt;/p&gt;   &lt;img src="tower.jpg"&gt;   &lt;p&gt; The text follows the normal flow &lt;/p&gt; &lt;/body&gt;</pre> </li> </ul>	<p><i>Francesco Marcelleni</i></p>  <p><i>Università di Pisa</i></p>	<p><i>Francesco Marcelleni</i></p> <h2>Visual Effects Visibility</h2> <ul style="list-style-type: none"> <li>■ 'visibility'</li> </ul>

For example, the 'se-resize' cursor is used when the movement starts from the south-east corner of the box.</li> </ul> </li> </ul> <p style="text-align: center;">201</p>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Visual Effects Cursor</h2> <ul style="list-style-type: none"> <li>'cursor' (continued)           <ul style="list-style-type: none"> <li>text - indicates text that may be selected. Often rendered as an I-beam.</li> <li>wait - indicates that the program is busy and the user should wait. Often rendered as a watch or hourglass.</li> <li>progress - a progress indicator. The program is performing some processing, but is different from 'wait' in that the user may still interact with the program. Often rendered as a spinning beach ball, or an arrow with a watch or hourglass.</li> <li>help - help is available for the object under the cursor. Often rendered as a question mark or a balloon.</li> </ul> </li> </ul> <p style="text-align: center;">202</p>
<p><i>Università di Pisa</i></p> <h2>Visual Effects Cursor</h2> <ul style="list-style-type: none"> <li>'cursor' (example)           <pre>&lt;head&gt; &lt;title&gt;   Examples of visual effects &lt;/title&gt; &lt;style type="text/css"&gt; div { cursor:text; width: 100px; height: 45px; } &lt;/style&gt; &lt;/head&gt; &lt;body&gt;   &lt;div&gt; The text too large results to be hidden &lt;/div&gt; &lt;/body&gt;</pre> </li> </ul> <p style="text-align: center;">203</p>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> <h2>Visual Effects Display</h2> <ul style="list-style-type: none"> <li>'display'           <p>Value: inline   block   list-item   run-in   inline-block   table   inline-table   table-row-group   table-header-group   table-footer-group   table-row   table-column-group   table-column   table-cell   table-caption   none   inherit</p> <p><b>Initial:</b> inline  <b>Applies to:</b> all elements  <b>Inherited:</b> no  <b>Percentages:</b> N/A  <b>Media:</b> all</p> <p>This property <b>is used to change the behavior of the elements</b>: for instance, it can be used to transform a paragraph into inline, that is, does not form a new block of content.</p> </li> </ul> <p style="text-align: center;">204</p>

## Visual Effects Display

- 'display'
  - **block** - this value causes an element to generate a block box.
  - **inline** - causes an element to generate one or more inline boxes.
  - **inline-block** - causes an element to generate a block box, which itself is flowed as a single inline box, similar to a replaced element. The inside of an inline-block is formatted as a block box, and the element itself is formatted as an inline replaced element.
  - **list-item** - causes an element (e.g., li in HTML) to generate a principal block box and a list-item inline box.

205

## Visual Effects Display

- 'display' (continued)
  - **none** - causes an element to not appear in the formatting structure (i.e., in visual media the element generates no boxes and has no effect on layout).
    - Descendant elements do not generate any boxes either; the element and its content are removed from the formatting structure entirely.
    - **This behavior cannot be overridden by setting the 'display' property on the descendants.**
  - **run-in** - this value creates either block or inline boxes, depending on context. Properties apply to run-in boxes based on their final status (inline-level or block-level).

207

## Visual Effects Display

- 'display' (continued)
  - **table, inline-table, table-row-group, table-column, table-column-group, table-header-group, table-footer-group, table-row, table-cell, and table-caption** - cause an element to behave like a table element.
  - Changing an inline element to a block element, or vice versa, can be useful for making the page look a specific way, and still follow web standards

```
li {display:inline;}
span {display:block;}
```

209

## Visual Effects Display

- <div style="width: 50px" ...> with different display

206

## Visual Effects Display

- 'display: run-in example'

```
h2 {
  font: normal 1.5em Georgia, serif;
  color: #454545;
  margin: 0 5px 5px 0;
  display: run-in;
  padding: 1px 1em;
  background: #ffc;
  border: 1px solid #999;
  border-radius: 6px;
}
```

</ul>
</body>
</html>
```

211

```
<style type="text/css">
  ul { list-style-type:none; margin:0; padding:0; }
  li {display:inline}
</style>
</head>
<body>
<ul>
  <li><a href="#home">Home</a></li>
  <li><a href="#news">News</a></li>
  <li><a href="#contact">Contact</a></li>
  <li><a href="#about">About</a></li>
</ul>
</body>
</html>
```

212

## Horizontal Navigation Bars

- Alternative solution

```
<style type="text/css">
a {display:inline}
</style>
</head>
<body>
<p><a href="#home">Home</a>
<a href="#news">News</a>
<a href="#contact">Contact</a>
<a href="#about">About</a></p>
</body>
```

213

## Vertical Navigation Bars

- To build a vertical navigation bar we only need to style the `<a>` elements, in addition to the code above:

```
a { display:block; }
```

214

## Tecnologie Web JavaScript

**Francesco Marcelloni**

Dipartimento di Ingegneria dell'Informazione  
Università di Pisa  
ITALY

1

## Scripting Languages

- Scripts offer authors a means to extend HTML documents in highly active and interactive ways. For example:
  - Scripts may be evaluated as a document loads to modify the contents of the document dynamically.
  - Scripts may accompany a form to process input as it is entered.
  - Scripts may be triggered by events that affect the document, such as loading, unloading, element focus, mouse movement, etc.
  - Scripts may be linked to form controls (e.g., buttons) to produce graphical user interface elements.

3

## Main Features

Strengths	Weakness
Quick Development	Limited Range of Built-in Methods
Easy to Learn	Generally, only client-side script
Platform Independence	No Code Hiding
Small Overhead	

5

## What is JavaScript?

- JavaScript is a **scripting language**.
- JavaScript **works on the client side**, which means that it runs on the user's computer and not on the Web server.
- JavaScript **is designed for use on Web pages** and is closely integrated with HTML.
- **JavaScript statements** embedded in an HTML page **can recognize and respond to User Events** such as Mouse Clicks, Form Input, and Page Navigation.

2

## Main Features

- Like all the scripting languages, JavaScript:
- is **interpreted** (easy to test program code, look at the results, make changes, and test it)
  - contains a **limited and easy-to-learn command set and syntax**
  - is designed for performing a well-defined set of tasks
  - is suited to **producing small programs**
  - is especially well designed for repetitive, event-invoked tasks
  - is **integrated into the browser** and can interact directly with the HTML pages
  - JavaScript makes it possible to **program responses to user events** such as mouse clicks and data entry in forms

4

## JavaScript Objectives

- To make **HTML pages dynamic, interactive and effective** through graphics and animations.
- To develop **client-side applications** with particular functions on the HTML object management
- To **validate the data input** from the users
- To **manage search tables** on the client
- To **store and retrieve** the cookies so as to obtain information on the client-server interaction

6

## JavaScript Standard

- JavaScript was invented by Netscape and was first used in Netscape browsers.
- Now, all the browsers support JavaScript
- **ECMAScript, standardized version of JavaScript, is documented in the ECMA-262 specification (5.1 Edition).**
- ECMA (European Computer Manufacturers Association). ECMA is an international standards association for information and communication systems.
- The **ECMA-262** standard is also approved by the ISO (International Organization for Standards) as **ISO-16262**.

7

## JavaScript versus Object-Oriented Languages

JavaScript	Java-C++
Object-based. Code uses built-in, extensible objects, but no classes or inheritance.	Object-oriented. Applets consist of object classes with inheritance.
Variable data types not declared (loose typing).	Variable data types must be declared (strong typing).
You can write fully-functional JavaScript using a simple text editor	To write fully-functional Java/C++, you need the Java/C++ Developer's Kit.

9

## How to insert a JavaScript into an HTML page?

- <script> tag
  - **src = uri**  
This attribute specifies the location of an external script.
  - **type = content-type**  
This attribute specifies the scripting language of the element's contents and overrides the default scripting language.
    - The scripting language is specified as a content type (e.g., "text/javascript").
    - Authors must supply a value for this attribute. There is no default value for this attribute.

11

## What cannot you do with JavaScript

- You **cannot access or write to server files**
- You do, however, have access to documents that are loaded into other browser windows and frames, provided that the documents are from the same server
- You also **cannot touch the local hard drive, send a print job, or edit the user's bookmarks or browser preferences**. NOTE: The exception are cookies – which JavaScript can read from the hard drive and write to the hard drive.

8

## How to insert a JavaScript into an HTML page?

- Use the <script> tag. Inside the <script> tag use the type attribute to define the scripting language.
 

```
<html>
<body>
<script type="text/javascript">
...
</script>
</body>
</html>
```
- The script element may appear any number of times in the head or body of an HTML document.

10

## How to insert a JavaScript into an HTML page?

- Example
  - The document.write command is a standard JavaScript command for writing output to a page.
  - By entering the document.write command between the <script> and </script> tags, the browser will recognize it as a JavaScript command and execute the code line.
 

```
<html>
<body>
<script type="text/javascript">
  document.write("Hello World!");
</script>
</body>
</html>
```

12

## How to handle simple browsers?

- Browsers that do not support JavaScript will display JavaScript as page content.
- To prevent them from doing this, and as a part of the JavaScript standard, the HTML comment tag should be used to "hide" the JavaScript.
- Just add an HTML comment tag <!-- before the first JavaScript statement, and a --> (end of comment) after the last JavaScript statement.

13

```
<html>
<body>
<script type="text/javascript">
<!--
document.write("Hello World!");
-->
</script>
</body>
</html>
```

## Where to insert the JavaScript Code

14

## Where to Put the JavaScript? Head solution

- When in the head, JavaScripts in a page will be executed immediately while the page loads into the browser.
- To prevent the automatic execution, the script has to be inserted into a function.
- Functions can be put in the head section, thus they do not interfere with page content

15

```
<html>
<head>
<script type="text/javascript">
function message()
{
alert("This alert box was called
with the onload event");
}
</script>
</head>
<body onload="message()">
</body>
</html>
```

## Where to Put the JavaScript? External File

- If you want to run the same JavaScript on several pages, without having to write the same script on every page, you can write a JavaScript in an external file.
- Save the external JavaScript file with a .js file extension.
- Note: The external script cannot contain any HTML tags (in particular, <script></script> tags!)

- To use the external script, point to the .js file in the "src" attribute of the <script> tag:

```
<html>
<head>
<script type="text/javascript"
src="xxx.js"></script>
</head>
<body>
</body>
</html>
```

17

## Where to Put the JavaScript? Body Solution (not recommended)

- If you don't want your script to be placed inside a function, or if your script should write page content, it should be placed in the body section
- You can place an unlimited number of scripts in your document, so you can have scripts in both the body and the head section.

16

```
<html>
<head>
</head>

<body>
<script type="text/javascript">
document.write("This message
is written by JavaScript");
</script>
</body>
</html>
```

Note: we could have problems whether different scripts depend on each other

## The default scripting language

- Authors should specify the default scripting language for all scripts in a document by including the following meta declaration in the head:

```
<meta http-equiv="Content-Script-Type" content="type">
```

where "type" is a content type naming the scripting language. Examples of values include "text/tcl", "text/javascript", "text/vbscript".

- The tag script allows using scripting languages different from the default.

18

## The noscript element

- The **noscript** element allows authors to provide alternate content when a script is not executed.
- Its content should only be rendered if:
  - The user agent is configured not to evaluate scripts.
  - The user agent does not support a scripting language invoked by a script element earlier in the document.
- Example:
 

```
<noscript> <meta http-equiv="Refresh" content="2"; url="paginasenzaJavaScript.html"></noscript>
```
- If the noscript element is rendered, the user is re-addressed after 2 seconds to the url specified in the noscript element
- Use both comments and the noscript element

19

## When is a script executed?

- Global code (not in the body of functions):
  - is executed when it is met during the rendering of the page. The global code can be in the HTML page or in an external file;
- Code in functions
  - is executed only if the function is called
- Event onLoad
  - The code corresponding to the event is executed when the page is loaded on the browser and **after** the execution of the code external to each function

20

## When is a script executed?

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="utf-8">
  <title>Execution order</title>
  <script type="text/javascript">
    <!-- HTML comment -->
```

21

## JavaScript Statements

23

## When is a script executed?

```
window.alert("Not in function");
document.write("<h1> This is a heading. </h1>");
document.write("<p>This is a paragraph.</p>");
document.write("<p>This is another paragraph.</p>");
function loading() { window.alert("onLoad event"); } -->
</script>
</head>
<body onLoad="loading()" >
<script type="text/javascript">
  window.alert("Code in Body");
</script>
</body>
</html>
```

22

## JavaScript Code

- JavaScript code is a sequence of Javascript statements
- A **JavaScript statement** is a command to a browser.
 

```
document.write("Hello Dolly");
```
- The **semicolon** is optional (according to the JavaScript standard), and the browser is supposed to interpret the end of the line as the end of the statement.
  - Note: Using semicolons makes it possible to write multiple statements on one line.
- **JavaScript is case sensitive**

24

## JavaScript Statements

- Statements are executed by the browser in the sequence they are written.

### Example

```
<script type="text/javascript">
<!-- document.write("<h1>Introduction</h1>");
document.write("<p>In this course we will introduce <a href='http://devedge-temp.mozilla.org/central/javascript/index_en.html'>
Javascript</a></p>"); 
document.write("<h2>Javascript Statements</h2>"); 
document.write("<p>A Javascript statement is ... </p>"); -->
</script>
</head>
<body><p>Example</p></body>
```

25

## JavaScript Comments

- Comments can be added to explain the JavaScript, or to make the code more readable.

- Single line comments start with //.
- Multi line comments start with /\* and end with \*/.

```
<script type="text/javascript">
/*
The code below will write one heading and two paragraphs
*/
document.write("<h1>This is a heading</h1>"); 
// Write a heading
document.write("<p>This is a paragraph.</p>"); //paragraph
document.write("<p>This is another paragraph.</p>"); 
</script>
```

27

## JavaScript Variables

- JavaScript allows declaring variables by simply using them
- Anyway, declaring variables helps to ensure that programs are well organized and helps to keep track of the scope of variables
- To declare JavaScript variables you can use the var statement

```
var x;
var carname;
```

After the declaration, the variables are empty (they have no value yet)

29

## JavaScript Blocks

- JavaScript statements can be grouped together in blocks.

- Blocks start with a left curly bracket { and ends with a right curly bracket }.
- The purpose of a block is to execute the sequence of statements together.

### Example

```
<script type="text/javascript">
{ document.write("<h1>This is a heading</h1>"); 
  document.write("<p>This is a paragraph.</p>"); 
  document.write("<p>This is another paragraph.</p>"); 
}
</script>
```

26

## JavaScript Variables

- Rules for JavaScript variable names:

- Variable names are case sensitive (y and Y are two different variables)
- The first character in the name must be a letter (a-z or A-Z) or an underscore (\_).
- The rest of the name can be made up of letters (a-z or A-Z), numbers (0-9), or underscores (\_).
- Names should describe what variables are.

- The type of the variable is not specified

28

## JavaScript Variables

- Variables can be initialized
 

```
var x=5;
var carname="Volvo";
```
- If you assign values to variables that have not been declared yet, the variables will automatically be declared.
- If you redeclare a JavaScript variable, it will not lose its original value.
 

```
var x=5;
var x;
```
- NOTE: the variable x will still have the value of 5. The value of x is not reset when you redeclare it.

30

## Loosely typed

- JavaScript is what is called a **loosely typed programming language**:

- the type of a variable is not defined when a variable is created and can, at times, change based on the context.

```
var text1 = "19";
var num1 = 96;
num1 = text1 + num1;
```

The variable num1 contains "1996".

31

## Numeric Values

- Integer

NUMBER SYSTEM	NOTATION
Decimal (base 10)	A normal integer without a leading 0 (zero) (ie, 752)
Octal (base 8)	An integer with a leading 0 (zero) (ie, 056)
<b>Hexadecimal (base 16)</b>	An integer with a leading 0x or 0X (ie, 0x5F or 0XC72)

- Floating Point Values

- 2.3e-3
- 2.3E-3

33

## String type

### Escape characters

	Character	Description
\n	new line	
\t	tab	
\r	carriage return	
\f	form feed	
\b	backspace	

**NOTE:** the escape characters only work in the following situations:

- within <pre> tags
- alert(), confirm() and prompt()
- within <textarea> tags

35

## Types of Values

- JavaScript recognizes the following types of values:

- Numeric
- String
- Boolean
- Null – a special keyword denoting a null value; null is also a primitive value
- Undefined – a top-level property whose value is undefined;
- undefined is also a primitive value (NaN in numeric contexts).

32

## String Values

- String

contains zero or more characters enclosed in **single or double quotes**

- NOTE: the empty string is distinct from the null value
- NOTE: Strings are different from other data types. Strings are actually Objects.
- The backslash (\) is used to insert apostrophes, new lines, quotes, and other special characters into a text string

Code	Outputs
\'	single quote
\\"	double quote
\&	ampersand
\\\	backslash

34

## Boolean and null Values

- boolean

- Note: Values of 1 and 0 are not considered Boolean values in JavaScript

- null Value

- Represents Nothing

- NaN – Not a Number (returned by some functions like parseInt() and parseFloat())

36

## Variable Scope

```
<script type="text/javascript">
<!-- HTML comment
var cc = 0 ;          //global
var dd = scr();        // global
document.writeln("global: " + cc); // print value of cc
document.writeln("local: " + dd); // print value of dd
function scr() {
    var cc = 3;        //local variable hides the global variable cc
    // without var, it would be an assignment to global variable cc
    return cc;
}
-->
</script>
</head>
```

37

## JavaScript Operators Assignment Operators

Operator	Example	Same As	Result
=	x=y		x=5
+=	x+=y	x=x+y	x=10
-=	x-=y	x=x-y	x=5
*=	x*=y	x=x*y	x=25
/=	x/=y	x=x/y	x=5
%=	x%=y	x=x%y	x=0

39

## JavaScript Operators Comparison Operators

- Given  $x=5$ , the table below explains the comparison operators

Operator	Description	Example
==	is equal to	$x==8$ is false $x=='5'$ is true
=====	is exactly equal to (value and type)	$x=====5$ is true $x===='5'$ is false
!=	is not equal (it attempts conversion)	$x!=8$ is true $x!=5$ is false
!==	is not equal and/or not of the same type	$x!==='5'$ is true
>	is greater than	$x>8$ is false
<	is less than	$x<8$ is true
>=	is greater than or equal to	$x>=8$ is false
<=	is less than or equal to	$x<=8$ is true

41

## JavaScript Operators Arithmetic Operators

- Let us assume that  $y=5$

Operator	Description	Example	Result
+	Addition	$x=y+2$	$x=7$
-	Subtraction	$x=y-2$	$x=3$
*	Multiplication	$x=y*2$	$x=10$
/	Division	$x=y/2$	$x=2.5$
%	Modulus (division remainder)	$x=y\%2$	$x=1$
++	Increment	$x=++y$ $x=y++$	$x=6$ $x=5$
--	Decrement	$x=--y$ $x=y--$	$x=4$ $x=5$

38

## JavaScript Operators The + Operator used on Strings

- The + operator can also be used to add string variables or text values together

```
txt1="This is a very";
txt2="nice day";
txt3=txt1+" "+txt2;
```

- Note: if you add a number and a string, the result will be a string

```
<script type="text/javascript">
x="5"+"5";
document.write(x);
document.write("<br>"); //55
x=5+"5";
document.write(x);
document.write("<br>"); //55
</script>
```

40

## JavaScript Operators Comparison Operators

- Comparison operators
  - If either or both values are NaN, then they are not equal.
  - Objects, arrays, and functions are compared by reference. This means that two variables are equal only if they refer to the same object.
  - If both are null, or both undefined, they are equal.
  - If one value is null and one undefined, they are equal.
- Two separate arrays are never equal by the definition of the == operator, even if they contain identical elements.

42

## JavaScript Operators Logical Operators

- Given  $x=6$  and  $y=3$ , the table below explains the logical operators

Operator	Description	Example
<code>&amp;&amp;</code>	and	<code>(x &lt; 10 &amp;&amp; y &gt; 1) is true</code>
<code>  </code>	or	<code>(x==5    y==5) is false</code>
<code>!</code>	not	<code>!(x==y) is true</code>

43

## JavaScript Operators

- If the types of the two values differ, attempt to convert them into the same type so they can be compared:
  - If one value is a **number** and the other is a **string**
    - convert the string to a number and try the comparison again, using the converted value.
  - If **either value is true**
    - convert it to 1 and try the comparison again.
  - If **either value is false**
    - convert it to 0 and try the comparison again.
  - If one value is an **object** and the other is a **number or string**
    - convert the object to a primitive value by either its `toString()` method or its `valueOf()` method. Native JavaScript classes attempt `valueOf()` conversions before `toString()` conversion.
  - Any other combinations of types are not equal.

45

## JavaScript Operators typeof operator

- typeof operator**
- Two ways:
  - `typeof operand`
  - `typeof (operand)`
- The **typeof operator returns a string indicating the type of the operand**. The parentheses are optional.
 

```
var num1 = 3; var num2 = 3.0;
var bool=true; var shape="round";
typeof num1; // returns number
typeof num2; // returns number
typeof bool; // returns boolean
typeof shape; // returns string
```

47

## JavaScript Operators Bitwise Operators

Operator	Description	Example
<code>&amp;</code>	and	<code>a &amp; b</code>
<code> </code>	or	<code>a   b</code>
<code>!</code>	xor	<code>a ^ b</code>
<code>~</code>	not	<code>~a</code>
<code>&lt;&lt;</code>	Left shift	<code>a&lt;&lt;b</code>
<code>&gt;&gt;</code>	Sign-propagating right shift	<code>a&gt;&gt;b</code>
<code>&gt;&gt;&gt;</code>	Zero-fill right shift	<code>a&gt;&gt;&gt;b</code>

44

## JavaScript Operators

- Conditional Operator**  
`(condition) ? val1 : val2`

Example:

```
var username = prompt("Please enter your name", "");
var greeting = "Hello ";
greeting += ((username != null) ? username : "guy");
```

46

## JavaScript Operators void operator

- void operator**
- Two ways:
  - `void (expression)`
  - `void expression`
- The **void operator specifies a JavaScript expression to be evaluated without returning a value**. The parentheses surrounding the expression are optional, but it is good style to use them.
- The following code creates a hypertext link that submits a form when the user clicks it.
 

```
<a href="javascript:void(document.form.submit())">
Click here to submit</a>
```

48

## Conditional Statements if statement

```
if (condition)
{
  code to be executed if condition is true
}
```

NOTE: "if" is written in lowercase letters. Using uppercase letters (IF) will generate a JavaScript error!

49

## Conditional Statements if ... else statement

```
if (condition)
{
  code to be executed if condition is true
}
else
{
  code to be executed if condition is not true
}
```

50

## Conditional Statements if ... else if ... else statement

```
if (condition1)
{
  code to be executed if condition1 is true
}
else if (condition2)
{
  code to be executed if condition2 is true
}
...
else
{
  code to be executed if condition1 and condition2 are not true
}
```

51

## Conditional Statements if ... else if ... else statement

```
<script type="text/javascript">
var d = new Date();
var time = d.getHours();
if (time<12)
{
  document.write("<em>Good morning</em>");
}
else if (time>=12 && time<17)
{
  document.write("<em>Good afternoon</em>");
}
else if (time>=17 && time<20)
{
  document.write("<em>Good evening</em>");
}
else
{
  document.write("<em>Good night!</em>");
}
</script>
```

52

## Conditional Statements switch statement

```
switch(n)
{
  case 1:
    execute code block 1
    break;
  case 2:
    execute code block 2
    break;
  default:
    code to be executed if n is different from case 1 and 2
}
```

53

## Conditional Statements switch statement

```
<head>
<meta charset="utf-8">
<title>Example</title>
<style type="text/css">
p {color: white; background-color: grey; }
p.sat {color: red; background-color: black; }
p.sun {color: green; background-color: red; }
</style>
<script type="text/javascript">
<!-- HTML comment
var d=new Date();
theDay=d.getDay();
```

54

## Conditional Statements switch statement

```
switch (theDay)
{ case 6:
    document.write("<p class='sat'>Super Saturday</p>");
    break;
case 0:
    document.write("<p class='sun'>Sleepy Sunday</p>");
    break;
default:
    document.write("<p>I'm looking forward to this weekend!</p>");
}
-->
</script>
</head>
```

55

## Loop statements while

```
while (var OP endvalue)
{
    code to be executed
}

where OP is any comparison operator.

Example
<script type="text/javascript">
var i=0;
while (i<=5)
    {document.write("<p>The number is " + i++ + "</p>");}
</script>
```

57

## Break statement

- The break statement will break the loop and continue executing the code that follows after the loop (if any).

```
<script type="text/javascript">
var i=0;
while (i<=5)
    { document.write("<p>The number is " + i++ + "</p>");}
    if (i==4) break;
</script>
</head>
```

59

## Loop statements for

```
for (var=startvalue;var OP endvalue;var=var+increment)
{
    code to be executed
}

where OP is any comparison operator.

Example
<script type="text/javascript">
var i=0;
for (i=0;i<=5;i++)
    { document.write("<p>The number is " + i + "</p>");}
</script>
```

56

## Loop statements do...while

```
do
{
    code to be executed
}
while (var OP endvalue);

where OP is any comparison operator.

Example
<script type="text/javascript">
var i=0;
do
    {document.write("<p>The number is " + i++ + "</p>");}
    while (i<=5)
</script>
```

58

## Continue statement

- The continue statement will break the current loop and continue with the next value

```
<script type="text/javascript">
var i=0;
for (i=0;i<=10;i++)
    { if (i%4) continue;
        document.write("<p>The number is " + i + "</p>");}
    }
```

60

## Label statement

- A **label** provides a statement with an identifier that lets you refer to it elsewhere in your program.  
label : statement
- The value of label may be any JavaScript identifier that is not a reserved word.
- On using label with break and continue
  - break [label]** - terminates the specified enclosing label statement
  - continue [label]** - restarts a label statement or continues execution of a labelled loop with the next iteration

61

## Loop statements for .. in

- The **for..in** statement loops through the elements of an array or through the properties of an object
- ```
for (variable in object)
{
  code to be executed
}
```
- Note: The code in the body of the for..in loop is executed once for each element/property.
  - Note: The variable argument can be a named variable, an array element (not an index), or a property (not the value of the property, but the name) of an object.

63

## with statement

- The **with** statement establishes the default object for a set of statements.
  - JavaScript looks up any unqualified names within the set of statements to determine if the names are properties of the default object. If an unqualified name matches a property, then the property is used in the statement; otherwise, a local or global variable is used.
  - A with statement looks as follows:
- ```
with (object){
  statements
}
```

```
var a, x, y;
var r=10;
with (Math) {
  a = PI * r * r;
  x = r * cos(PI);
  y = r * sin(PI/2);
}
```

65

## continue statement (example)

```
var i=0, j=8;
checki : while (i<8) {
  document.write("<p>i = " + i + "</p>");
  checkj : while (j>0) {
    j--;i++;
    if ((j%3)==0) continue checki;
    if ((j%2)==0) continue checkj;
    document.write("<p>j = " + j + " is odd.</p>");
  }
}
```

62

## Loop statements for .. in

```
<script type="text/javascript">
<!-- HTML comment
var x;
var mycars = new Array();
mycars[0] = "Saab";
mycars[1] = "Volvo";
mycars[2] = "BMW";

for (x in mycars)
  document.write("&lt;p&gt;" + x + ": " + mycars[x] + "&lt;/p&gt;");

--&gt;
&lt;/script&gt;</pre>

```

64

## Functions

```
function name(var1,var2,...,varX)
{
  var x;
  some code
  return x;
}
```

- You may call a function from anywhere within a page (or even from other pages if the function is embedded in an external .js file).
- Functions can be defined both in the <head> and in the <body> section of a document. However, to assure that a function is read-loaded by the browser before it is called, it could be wise to put functions in the <head> section.

66

## Functions

- All parameters are passed to functions by value; the value is passed to the function, but if the function changes the value of the parameter, this change is not reflected globally or in the calling function.
- Objects are passed by reference: if the function changes the object's properties, that change is visible outside the function.
- A function can even be recursive, that is, it can call itself.

67

## Functions

- The arguments of a function are maintained in the array "arguments".
- Within a function, you can address the parameters passed to it by:  
`arguments[i]`  
`functionName.arguments[i]`
- where i is the ordinal number of the argument, starting at zero.  
`arguments[0]` -> the first argument passed to a function.
- The total number of arguments is indicated by `arguments.length`.

69

## Functions

```
<script type="text/javascript">
<!-- HTML comment
function myConcat(separator) {
result = ""; // initialize list
// iterate through arguments
for (var i=1; i<arguments.length; i++) {
result += arguments[i] + separator;
}
result += "<br>";
return result;
}
-->
</script>
</head>
```

71

## Functions

```
<script type="text/javascript">
function fun(s) { // function definition
var a = 10;
var c = 10 * s;
document.write("<p>This is the result: " + c + "</p>");
}
</script>
</head>

<body onLoad="fun(10)">
<!-- call to the function fun -->
<script type="text/javascript">
window.alert("Code in Body");
</script>
```

68

## Functions

- Using the arguments array, you can call a function with more arguments than it is formally declared to accept.
  - This is often useful if you do not know in advance how many arguments will be passed to the function.
  - You can use `arguments.length` to determine the number of arguments actually passed to the function, and then treat each argument using the arguments array.
- No check on the order of the parameters

70

## Functions

```
<body>
<script type="text/javascript">
<!-- HTML comment
// returns "red, orange, blue,
document.write(myConcat(", ", "red", "orange", "blue"));
// returns "elephant; giraffe; lion; cheetah;
document.write(myConcat(";", "elephant", "giraffe", "lion", "cheetah"));
// returns "sage. basil. oregano. pepper. parsley."
document.write(myConcat(".", "sage", "basil", "oregano", "pepper",
"parsley"));
-->
</script>
```

72

## The return statement

- The return statement is used to specify the value that is returned from the function.

```
<head>
<script type="text/javascript">
function product(a,b)
{ return a*b; }
</script>
</head>
<body>
<script type="text/javascript">
document.write(product(4,3));
</script>
```

73

## Predefined functions

- parseInt(string,radix)**  
Parses a string and returns an integer of the specified radix (base).  
radix - a number (from 2 to 36) that represents the numeral system to be used
- parseFloat(string)**  
Parse a string and returns a float number.  
If the first character cannot be converted to a number, the two functions return NaN.
- number(object) and string(object)**  
Converts the object argument to a number or to a string that represent the object's value.  
If the value cannot be converted to a legal number, NaN is returned.

75

## Predefined functions

- escape(string) and unescape(string)**  
The escape() function encodes a string. This function makes a string portable, so it can be transmitted across any network to any computer that supports ASCII characters. This function encodes special characters, with the exception of: \* @ - \_ + . /  
The unescape() function decodes an encoded string.

```
<script type="text/javascript">
<!-- HTML comment
str="Need tips? Visit W3Schools!";
str_esc=escape(str);
document.write(str_esc + "<br>");
document.write(unescape(str_esc));
-->
</script>
```

77

## Predefined functions

- JavaScript has several top-level predefined functions:
  - eval(string)** - Evaluates a string and executes it as if it was script code  
`eval("x=10;y=20;document.write(x*y)"); //200`
  - isFinite** - Determines whether a value is a finite, legal number  
`document.write(isFinite(123)+ "<br>"); //true`  
`document.write(isFinite("2005/12/12") + "<br>"); //false`
  - isNaN** - The isNaN() function determines whether a value is an illegal number (Not-a-Number).  
This function returns true if the value is NaN, and false if not.
    - `document.write(isNaN(123)+ "<br>"); //false`
    - `document.write(isNaN("2005/12/12") + "<br>"); //true`

74

## Predefined functions

```
<body>
<script type="text/javascript">
<!-- HTML comment
eval("x=10;y=20;document.write(x*y)");
document.write("<br>" + isFinite(123) + "<br>");
document.write(isFinite("2005/12/12") + "<br>");
document.write(isNaN(123) + "<br>");
document.write(isNaN("2005/12/12") + "<br>");
document.write(parseInt("His age is 40 years") + "<br>");
document.write(parseInt("40 years") + "<br>");
-->
</script>
</body>
```

76

## document.write() and document.writeln() methods

- document.write(exp1,exp2,exp3,...)**  
The write() method writes HTML expressions or JavaScript code to a document.  
Multiple arguments can be listed and they will be appended to the document in order of occurrence
- document.writeln(exp1,exp2,exp3,...)**  
The writeln() method is identical to the write() method, with the addition of writing a newline character after each statement.

Since HTML ignores the newline characters, **the effects of the methods on the HTML pages are equal except when used within <pre> tags**

78

## The document.write() and document.writeln() methods

```
<body>
<pre>
<script type="text/javascript">
  document.write("Hello World!");
  document.write("Have a nice day!");
</script>
</pre>
<pre>
<script type="text/javascript">
  document.writeln("Hello World!");
  document.writeln("Have a nice day!");
</script>
</pre>
</body>
```

79

## Popup Boxes Alert Box

```
<script type="text/javascript">
function show_alert()
{ alert("I am an alert box!");}
</script>
</head>
<body>
<p><input type="button" onclick="show_alert()" value="Show alert box">
</p>
</body>
```

81

## Popup Boxes Confirm Box

```
<script type="text/javascript">
function show_confirm()
{ var r=confirm("Press a button!");
  if (r==true)
    { alert("You pressed OK!"); }
  else
    { alert("You pressed Cancel!"); }
}
</script>
```

83

## Popup Boxes Alert Box

- An **alert box** is often used if you want to make sure information comes through to the user.
- When an alert box pops up, the user will have to click "OK" to proceed.

```
alert("sometext");
```

80

## Popup Boxes Confirm Box

- A **confirm box** is often used if you want the user to verify or accept something.
- When a confirm box pops up, the user will have to click either "OK" or "Cancel" to proceed.
- If the user **clicks "OK"**, the box **returns true**. If the user **clicks "Cancel"**, the box returns **false**.

```
confirm("sometext");
```

82

## Popup Boxes Prompt Box

- A **prompt box** is often used if you want the user to input **a value before entering a page**.
- When a prompt box pops up, the user will have to click either "OK" or "Cancel" to proceed after entering an input value.
- If the user **clicks "OK"** the box **returns the input value**. If the user **clicks "Cancel"** the box **returns null**.

```
prompt("sometext","defaultvalue");
```

84

## Popup Boxes Prompt Box

```
<script type="text/javascript">
function show_prompt()
{ var name=prompt("Please enter your name","Harry Potter");
  if (name!=null && name!="")
    { document.write("Hello " + name + "! How are you today?"); }
}
</script>
</head>
<body>
<input type="button" onclick="show_prompt()" value="Show
prompt box">
</body>
```

85

## Catching Errors try...catch statement

```
try { myroutine(); // may throw three exceptions
}
catch (e if e instanceof TypeError) {
  // statements to handle TypeError exceptions
}
catch (e if e instanceof RangeError) {
  // statements to handle RangeError exceptions
}
catch (e if e instanceof EvalError) {
  // statements to handle EvalError exceptions
}
catch (e){
  // statements to handle any unspecified exceptions
  logMyErrors(e) // pass exception object to error handler
}
```

87

## Catching Errors try...catch statement

```
<body>
<div>
<input type="button" value="View
message" onclick="message()"/>
</div>
</body>
```

89

## Catching Errors try...catch statement

```
try
{
  //Run some code here
}
catch(err if expression)
{
  //Handle errors here
}

■ The try...catch statement allows you to test a block of code for
errors.

■ The try block contains the code to be run, and the catch block
contains the code to be executed if an error occurs.

■ err is initialized with the exception object

■ expression is a test expression
```

86

## Catching Errors try...catch statement

```
<script type="text/javascript">
function message()
{ try { addAlert("Welcome guest!"); }
  catch(err)
  { var txt="There was an error on this page.\n\n";
    txt+="Click OK to continue viewing this page,\n";
    txt+="or Cancel to return to the home page.\n\n";
    if(!confirm(txt))
      { document.location.href=
"http://devedge-temp.mozilla.org/central/javascript/index_en.html";
    }
  }
}
</script></head>
```

88

## Catching Errors Throw statement

- The throw statement allows you to create an exception.

```
throw(exception)

■ The exception can be a string, integer, Boolean or an object.

<body>
<script type="text/javascript">
var x=prompt("Enter a number between 0 and 10:","");
try
{ if(x>10)
  { throw "Err1"; }
  else if(x<0)
  { throw "Err2"; }
  else if(isNaN(x))
  { throw "Err3"; }
}
```

90

## Catching Errors Throw statement

```
catch(er)
{ if(er=="Err1")
  { alert("Error! The value is too high"); }
if(er=="Err2")
{ alert("Error! The value is too low"); }
if(er=="Err3")
{ alert("Error! The value is not a number"); }
}
</script>
</body>
```

91

## JavaScript Objects

## JavaScript Objects

- No inheritance
  - No private properties and methods
  - Both the object name and property name are case sensitive.
  - You define a property by assigning it a value.
    - For example, suppose there is an object named myCar (for now, just assume the object already exists). You can give it properties named make, model, and year as follows:
- ```
myCar.make = "Ford";
myCar.model = "Mustang";
myCar.year = 1969;
```

93

## JavaScript Objects

- Associative array notation (example)

```
function show_props(obj, obj_name) {
  var result = "";
  for (var i in obj) // i assumes as values all the property names
  result += obj_name + "." + i + " = " + obj[i] + "\n";
  return result
}
```

The function call `show_props(myCar, "myCar")` returns

```
myCar.make = Ford
myCar.model = Mustang
myCar.year = 1967
```

95

## JavaScript Objects Creating new objects

- Two ways for creating objects
  - use an **object initializer**
  - create a **constructor function** and then instantiate an object using that function and the new operator.
- The first way is useful when you need to create a unique instance of the object; otherwise use the second way.

96

## JavaScript Objects Object Initializer

- Object initializer

`objectName = {property1:value1,..., propertyN:valueN}`

`objectName`: name of the new object

`propertyI`: identifier (either a name, a number, or a string literal),  
`valueI`: expression whose value is assigned to the propertyI.

The **property of an object can be an object** in its turn.

The `objectName` and assignment is optional. If you do not need to refer to this object elsewhere, you do not need to assign it to a variable.

Note: **new properties can be added dynamically**

`objectName.newproperty=value`

97

## JavaScript Objects Constructor Function

- Constructor Function

1. Define the **object type** by writing a constructor function.
2. Create an instance of the object with `new`.

To define an object type, **create a function for the object type that specifies its name, properties, and methods.**

```
function Car(make, model, year) {
  this.make = make
  this.model = model
  this.year = year
}
```

```
mycar = new Car("Eagle", "Talon TSi", 1993)
kenscar = new Car("Nissan", "300ZX", 1992)
vpgscar = new Car("Mazda", "Miata", 1990)
```

99

## JavaScript Operators new operator

- new operator

You can use the `new` operator to create **an instance of a user-defined object type or of one of the predefined object types Array, Boolean, Date, Function, Image, Number, Object, Option, RegExp, or String.**

```
objectName = new objectType (param1 [,param2]
...[,paramN]);
```

101

## JavaScript Objects Object Initializer

- Object initializer (example)

```
guy = { name: "Paul",
  age: 40,
  country: "Italy",
  auto: { trademark: "Ferrari", colour: "rosso" }}
```

...

```
<pre>
<script type="text/javascript">
for (var a in guy)
  if (typeof(guy[a])=="object")
    for (var i in guy[a])
      document.writeln(a + ':' + i + ':' + guy[a][i]);
  else document.writeln(a + ':' + guy[a]);
</script>
</pre>
```

98

## JavaScript Objects Constructor Function

- Constructor Function

An object can **have a property that is itself another object.**

```
function Person(name, age, sex) {
  this.name = name
  this.age = age
  this.sex = sex
}
function Car(make, model, year, owner) {
  this.make = make
  this.model = model
  this.year = year
  this.owner = owner
}
owner = new Person("Frankie Black", 45, "M")
mycar = new Car("Eagle", "Talon TSi", 1993, owner)
```

100

## JavaScript Objects Adding a new property

- Properties can be added to an object at run time.

- To add a property to a specific object you have to assign a value to the object

```
car1.enginepower = 100
```

- Note: **only the car1 object will have the property enginepower**

102

## JavaScript Object Types Adding a new property

- You can **add a property to a previously defined object type** by using the **prototype** property.
- This defines a property that is shared by all objects of the specified type, rather than by just one instance of the object.
- The following code adds a color property to all objects of type car, and then assigns a value to the color property of the object car1.

```
Car.prototype.color=null
car1.color="black"
```

103

## JavaScript Object Types Adding a new property

```
<script type="text/javascript"><!-- HTML comment
owner = new Person("Frankie Black",45,"M")
mycar1 = new Car("Eagle", "Talon TSi", 1993, owner)
displayCar(mycar1)
Car.prototype.color="red"
mycar2 = new Car("Nissan", "300ZX", 1992,owner)
mycar3 = new Car("Mazda", "Miata", 1990,owner)
mycar3.color = "black"
displayCar(mycar1)
displayCar(mycar2)
displayCar(mycar3) -->
```

105

## JavaScript Objects Defining methods

```
function displayCar(){
for (var a in this)
if (typeof(this[a])=="object")
  for (var i in this[a]) document.writeln(a + '!' + i + ':' + this[a][i]);
else if (typeof(this[a])!="function") document.writeln(a+':'+this[a]);
document.writeln();
}

function Car(make, model, year, owner) {
  this.make = make;
  this.model = model;
  this.year = year;
  this.owner = owner;
  this.displayCar = displayCar;
}
```

107

## JavaScript Object Types Adding a new property

```
<head>
<meta http-equiv="Content-type" content="text/html; charset=ISO-8859-1">
<meta http-equiv="Content-Script-Type" content="text/javascript">
<title>Example</title>
<script type="text/javascript"><!--
function displayCar(car)
{ for (var a in car)
  if (typeof(car[a])=="object")
    for (var i in car[a])
      document.writeln(a + '!' + i + ':' + car[a][i]);
  else document.writeln(a+':'+car[a]);
  document.writeln();
}
-->
</script></head>
```

104

## JavaScript Objects Defining methods

- The following syntax **associates a function with an existing object**:
`object.methodname = function_name`
- You can then call the method in the context of the object as follows:
`object.methodname(params);`
- You can define methods for an object type by including a method definition in the object constructor function.**

106

## JavaScript Objects Defining methods

```
<script type="text/javascript">
<!-- HTML comment
owner = new Person("Frankie Black",45,"M")
mycar1 = new Car("Eagle", "Talon TSi", 1993, owner)
mycar1.displayCar();
Car.prototype.color="red"
mycar2 = new Car("Nissan", "300ZX", 1992,owner)
mycar3 = new Car("Mazda", "Miata", 1990,owner)
mycar3.color = "black"
mycar1.displayCar();
mycar2.displayCar();
mycar3.displayCar();
-->
</script>
```

108

## JavaScript Objects Defining methods

Alternatively

```
function Car(make, model, year, owner) {
    this.make = make;
    this.model = model;
    this.year = year;
    this.owner = owner;
}
```

```
Car.prototype.displayCar = function () {
    for (var a in this)
        if (typeof(this[a])=="object")
            for (var i in this[a]) document.writeln(a + '.' + i + ':' + this[a][i]);
        else if (typeof(this[a])!="function") document.writeln(a+'!'+this[a]);
        document.writeln();
}
```

109

## JavaScript Operators delete operator

- delete operator (example)

```
x=42;
var y= 43;
myobj=new Number();
myobj.h=4; // create property
delete x; // returns true (can delete if declared implicitly)
delete y; // returns false (cannot delete if declared with var)
delete Math.PI; // returns false (cannot delete predefined properties)
delete myobj.h; // returns true (can delete user-defined properties)
delete myobj; // returns true (delete user-defined object)
var myobj1=new Number();
window.alert(delete myobj1); //returns false (cannot delete if declared with var)
```

111

## Inheritance

113

## JavaScript Operators delete operator

`delete objectName`  
`delete objectName.property`  
`delete objectName[index]`  
`delete property` // legal only within a "with" statement

where `objectName` is the name of an object, `property` is an existing property, and `index` is an integer representing the location of an element in an array.

- If the `delete operator succeeds`, it sets the property or element to `undefined`.
- The `delete operator` returns `true` if the operation is possible; it returns `false` if the operation is not possible.
- You can use the `delete operator` to delete variables declared implicitly but not those declared with the `var` statement.

110

## JavaScript Operators delete operator

- delete operator (array elements)

When you `delete` an array element, the array `length` is not affected. For example, if you `delete a[3]`, `a[4]` is still `a[4]` and `a[3]` is `undefined`.

When the `delete operator` removes an array element, that element is no longer in the array.

```
trees=new Array("redwood","bay","cedar","oak","maple");
delete trees[3];
if (3 in trees) {
    // this does not get executed
}
trees[3] = "oak";
if (3 in trees) {
    // this does get executed
}
```

112

## JavaScript Objects Inheritance

- JavaScript implements inheritance by allowing you to associate a prototypical object with any constructor function.

114

## JavaScript Objects Inheritance

- When you create a new Manager, it inherits the name and dept properties from the Employee object.

115

## JavaScript Objects Inheritance

```

function display(obj)
{ for (var a in obj)
  {   document.write(a);
      if (typeof(obj[a])=="object" && obj[a].length!=0)
      {   document.write("."); display(obj[a]);}
      else   document.writeln(' = ' + obj[a]);
  }
}
salesP = new SalesPerson;
display(salesP);
document.writeln();
eng = new Engineer;
display(eng);
  
```

117

## JavaScript Objects Inheritance – adding properties

- Constructors with arguments

### Default values

119

## JavaScript Objects Inheritance

- The `new` operator creates a new generic object and passes this new object as the value of the `this` keyword to the constructor function.

- When you ask for the value of a property, JavaScript first checks to see if the value exists in that object.

- If it does, that value is returned.
- If the value is not there locally, JavaScript checks the prototype chain (using the `__proto__` property).
  - If an object in the prototype chain has a value for the property, that value is returned.
  - If no such property is found, JavaScript says the object does not have the property.

116

## JavaScript Objects Inheritance – adding properties

- If you add a new property to an object that is being used as the prototype for a constructor function, you add that property to all objects that inherit properties from the prototype.

118

## JavaScript Objects Inheritance – adding properties

- Constructors with arguments

120

## JavaScript Objects

### Inheritance – adding properties

- Note: The name of the base property is not special. You can use any legal property name; base is simply evocative of its purpose.
- Note: call the WorkerBee constructor from inside the Engineer constructor does not set up inheritance appropriately for Engineer objects.
  - Calling the WorkerBee constructor ensures that an Engineer object starts out with the properties specified in all constructor functions that are called. However, if you later add properties to the Employee or WorkerBee prototypes, those properties are not inherited by the Engineer object.

121

## JavaScript Objects

### Inheritance – adding properties

- For example, assume you have the following statements:
 

```
function Engineer (name, projs, mach) {
  this.base = WorkerBee; this.base(name, "engineering", projs);
  this.machine = mach || "";
```
- jane = new Engineer("Doe, Jane", ["navigator", "javascript"], "belau");
 

```
Employee.prototype.specialty = "none";
```

  - The jane object does not inherit the specialty property.
- ```
Engineer.prototype = new WorkerBee;
```

jane = new Engineer("Doe, Jane", ["navigator", "javascript"], "belau");

```
Employee.prototype.specialty = "none";
```

  - Now, the value is inherited

122

## Built-in Objects

123

## Built-in Objects

### Array

- An array is an ordered set of values that you refer to with a name and an index.
- Array elements may belong to different types
- The Array object has methods for manipulating arrays in various ways, such as joining, reversing, and sorting them.
  - It has a property for determining the array length and other properties for use with regular expressions.

125

## Objects

- Predefined built-in objects
  - Array, Boolean, Date, Function, Math, Number, RegExp, and String
- Predefined client-side objects
  - When you load a document in Navigator, it creates a number of JavaScript objects with property values based on the HTML in the document and other pertinent information.
  - These objects exist in a hierarchy that reflects the structure of the HTML page itself.
  - Each page has always the objects: Navigator, Window, Document, Location, History.

124

## Built-in Objects

### Array

#### Create an Array

Three forms

- ```
var myCars=new Array(); // (add an optional integer
myCars[0]="Saab"; // argument to control array's size)
myCars[1]="Volvo";
myCars[2]="BMW";
```
- ```
var myCars=new Array("Saab","Volvo","BMW"); //condensed
```
- ```
var myCars=["Saab","Volvo","BMW"]; //literal array
  ■ It is also possible to avoid to specify all the values of the
elements of the array
  var myCars=["Saab", , "BMW"];
```

126

## Built-in Objects Array

- Access an Array  
`document.write(myCars[0]);`
  - Modify values in an Array  
`myCars[0] = "Opel";`
  - An array can dynamically be extended  
`myCars[6] = "Fiat";`
- The size of the array is extended to 7. The elements with indexes 3, 4 and 5 are undefined.

127

## Built-in Objects Array

### ■ Array properties

Property	Description
<code>constructor</code>	Returns the function that created the Array object's prototype
<code>length</code>	Sets or returns the number of elements in an array
<code>prototype</code>	Allows you to add properties and methods to an object

128

## Built-in Objects Array

Method	Description
<code>concat()</code>	Joins two or more arrays, and returns a copy of the joined arrays <code>array.concat(array2, array3, ..., arrayX)</code>
<code>join()</code>	Joins all elements of an array into a string <code>array.join(separator)</code> If the separator is omitted, the elements are separated with a comma
<code>pop()</code>	Removes the last element of an array, and returns that element <code>array.pop()</code>
<code>push()</code>	Adds new elements to the end of an array, and returns the new length <code>array.push(element1, element2, ..., elementX)</code>

129

## Built-in Objects Array

Method	Description
<code>sort()</code>	Sorts the elements of an array <code>array.sort(sortfunc)</code> <code>sortfunc</code> Optional. A function that defines the sort order Default: sorts the elements alphabetically and ascending. However, numbers will not be sorted correctly (40 comes before 5). To sort numbers, you must add a function that compare numbers
<code>splice()</code>	Adds/Removes elements from an array <code>array.splice(index, howmany, element1, ..., elementX)</code> <code>index</code> Required. An integer that specifies at what position to add/remove elements <code>howmany</code> Required. The number of elements to be removed. If set to 0, no elements will be removed <code>element1, ..., elementX</code> Optional. The new element(s) to be added to the array

131

## Built-in Objects Array

Method	Description
<code>reverse()</code>	Reverses the order of the elements in an array <code>array.reverse()</code>
<code>shift()</code>	Removes the first element of an array, and returns that element <code>array.shift()</code>
<code>slice()</code>	Selects a part of an array, and returns the new array <code>array.slice(start, end)</code> <code>start</code> Required. An integer that specifies where to start the selection. You can also use negative numbers to select from the end of an array <code>end</code> Optional. An integer that specifies where to end the selection. If omitted, slice() selects all elements from the start position and to the end of the array

130

## Built-in Objects Array

Method	Description
<code>toString()</code>	Converts an array to a string, and returns the result <code>array.toString()</code>
<code>unshift()</code>	Adds new elements to the beginning of an array, and returns the new length <code>array.unshift(element1, element2, ..., elementX)</code> <code>element1, element2, ..., elementX</code> Required. The element(s) to add to the beginning of the array
<code>valueOf()</code>	Returns the primitive values of an array <code>array.valueOf()</code>

132

## Built-in Objects Array

### ■ Sort numbers

```
<script type="text/javascript">
function sortNumber(a,b)
{
    return a - b;          //numerically and ascending)
    //return b - a; (numerically and descending)
}
var n = [10, 5, 40, 25, 100, 1];
document.write(n.sort(sortNumber));
</script>
```

133

## Built-in Objects Array

```
function invert()
{ myvector.reverse();
  print(myvector, "(invert)");
}

function shift()
{ myvector.shift();
  print(myvector,"(translate)");
}

function sort()
{ myvector.sort();
  print(myvector,"(sort)");
}
```

135

## Built-in Objects Array

```
<body>
<form action="#">
<p>Add a new element: <input type="text" name="text1">
<input type="button" value="ADD" onclick="add()"><br>
<input type="button" value="JOIN('+')"
      onclick="concatenate()"><br>
<input type="button" value="INVERT" onclick="invert()"><br>
<input type="button" value="SHIFT" onclick="shift()"><br>
<input type="button" value="SORT" onclick="sort()"><br>
</p>
</form>
</body>
```

137

## Built-in Objects Array

### ■ Example

```
<script type="text/javascript"><!--
var myvector= new Array("S","D","A","B");
print(myvector,"(initialise)");

function add()
{   myvector[myvector.length] = document.forms[0].text1.value;
  print(myvector, "(add)");
}

function concatenate()
{   var vector = myvector.join("+");
  document.writeln(vector+ "<br>(concatenate)");
}
```

134

## Built-in Objects Array

```
function print(vector, comment)
{   for (var i = 0; i < vector.length; i++)
    document.writeln(vector[i]);
    document.writeln("<br>" + comment);
}
-->
</script>
</head>
```

136

## Built-in Objects Boolean

### ■ The Boolean object is a wrapper around the primitive Boolean data type.

- booleanObjectName = new Boolean(value)
- If the Boolean object has no initial value or if it is 0, -0, null, "", false, undefined, or NaN, the object is set to false. Otherwise it is true (even with the string "false")!
- It is used to convert a non-boolean value into a boolean value.

Method	Description
<code>toString()</code>	Converts a Boolean value to a string, and returns the result
<code>valueOf()</code>	Returns the primitive value of a Boolean object

138

## Built-in Objects

### Date

- JavaScript stores dates as the number of milliseconds since January 1, 1970, 00:00:00
- Four forms to create a Date object
  - `new Date () // Date object with current date and time`
  - `new Date (milliseconds) //milliseconds since 1970/01/01`
  - `new Date (dateString) //A string representing a date in the following form: "Month day, year hours:minutes:seconds." For example, Xmas95 = new Date("December 25, 1995 13:30:00"). If you omit hours, minutes, or seconds, the value will be set to zero.`
  - `new Date (year, month, day, hours, minutes, seconds, milliseconds) //parameters are integer values`
- Most parameters above are optional. Not specifying them, causes 0 to be passed in.

139

## Built-in Objects

### Date

Method	Description
<code>getUTCDate()</code>	Returns the day of the month, according to universal time (from 1-31). UTC (Coordinated Universal Time) is an atomic timescale that approximates UT1.
<code>getUTCDay()</code>	Returns the day of the week, according to universal time (from 0-6)
<code>getUTCFullYear()</code>	Returns the year, according to universal time (four digits)
<code>getUTCHours()</code>	Returns the hour, according to universal time (from 0-23)
<code>getUTCMilliseconds()</code>	Returns the milliseconds, according to universal time (from 0-999)
<code>getUTCMinutes()</code>	Returns the minutes, according to universal time (from 0-59)
<code>getUTCMonth()</code>	Returns the month, according to universal time (from 0-11)
<code>getUTCSeconds()</code>	Returns the seconds, according to universal time (from 0-59)

141

## Built-in Objects

### Date

Method	Description
<code>setUTCDate()</code>	Sets the day of the month, according to universal time (from 1-31)
<code>setUTCFullYear()</code>	Sets the year, according to universal time (four digits)
<code>setUTCHours()</code>	Sets the hour, according to universal time (from 0-23)
<code>setUTCMilliseconds()</code>	Sets the milliseconds, according to universal time (from 0-999)
<code>setUTCMinutes()</code>	Set the minutes, according to universal time (from 0-59)
<code>setUTCMonth()</code>	Sets the month, according to universal time (from 0-11)
<code>setUTCSeconds()</code>	Set the seconds, according to universal time (from 0-59)

143

## Built-in Objects

### Date

Method	Description
<code>getDate()</code>	Returns the day of the month (from 1-31)
<code>getDay()</code>	Returns the day of the week (from 0-6)
<code>getFullYear()</code>	Returns the year (four digits)
<code>getHours()</code>	Returns the hour (from 0-23)
<code>getMilliseconds()</code>	Returns the milliseconds (from 0-999)
<code>getMinutes()</code>	Returns the minutes (from 0-59)
<code>getMonth()</code>	Returns the month (from 0-11)
<code>getSeconds()</code>	Returns the seconds (from 0-59)
<code>getTime()</code>	Returns the number of milliseconds since midnight Jan 1, 1970

140

## Built-in Objects

### Date

Method	Description
<code>parse()</code>	Parses a date string and returns the number of milliseconds since midnight of January 1, 1970 <code>Date.parse(datestring)</code> Datestring Required. A string representing a date
<code> setDate()</code>	Sets the day of the month (from 1-31)
<code>setFullYear()</code>	Sets the year (four digits)
<code>setHours()</code>	Sets the hour (from 0-23)
<code>setMilliseconds()</code>	Sets the milliseconds (from 0-999)
<code>setMinutes()</code>	Set the minutes (from 0-59)
<code>setMonth()</code>	Sets the month (from 0-11)
<code>setSeconds()</code>	Sets the seconds (from 0-59)
<code>setTime()</code>	Sets a date and time by adding or subtracting a specified number of milliseconds to/from midnight January 1, 1970

142

## Built-in Objects

### Date

Method	Description
<code>toDateString()</code>	Converts the date portion of a Date object into a readable string
<code>toLocaleDateString()</code>	Returns the date portion of a Date object as a string, using locale conventions
<code>toLocaleTimeString()</code>	Returns the time portion of a Date object as a string, using locale conventions
<code>toLocaleString()</code>	Converts a Date object to a string, using locale conventions
<code>toString()</code>	Converts a Date object to a string
<code>toTimeString()</code>	Converts the time portion of a Date object to a string
<code>toUTCString()</code>	Converts a Date object to a string, according to universal time
<code>UTC()</code>	Returns the number of milliseconds in a date string since midnight of January 1, 1970, according to universal time
<code>valueOf()</code>	Returns the primitive value of a Date object

144

## Built-in Objects Date

```
<script type="text/javascript">
    var d=new Date();
    document.write("Original form: ");
    document.write(d + "<br>");
    document.write("Formatted form: ");
    document.write(d.toLocaleDateString());
</script>
```

**Output**

Original form: Mon May 17 16:46:50 UTC+0200 2010

Formatted form: lunedì 17 maggio 2010

145

## Built-in Objects Math

- Note: Case-Sensitive

Property	Description
E	Returns Euler's number (approx. 2.718)
LN2	Returns the natural logarithm of 2 (approx. 0.693)
LN10	Returns the natural logarithm of 10 (approx. 2.302)
LOG2E	Returns the base-2 logarithm of E (approx. 1.442)
LOG10E	Returns the base-10 logarithm of E (approx. 0.434)
PI	Returns PI (approx. 3.14159)
SQRT1_2	Returns the square root of 1/2 (approx. 0.707)
SQRT2	Returns the square root of 2 (approx. 1.414)

147

## Built-in Objects Math

Method	Description
floor(x)	Returns x, rounded downwards to the nearest integer
log(x)	Returns the natural logarithm (base E) of x
max(x,y,z,...,n)	Returns the number with the highest value
min(x,y,z,...,n)	Returns the number with the lowest value
pow(x,y)	Returns the value of x to the power of y
random()	Returns a random number between 0 and 1
round(x)	Rounds x to the nearest integer
sin(x)	Returns the sine of x (x is in radians)
sqrt(x)	Returns the square root of x
tan(x)	Returns the tangent of an angle

149

## Built-in Objects Math

- The Math object allows performing mathematical tasks.
- The Math object includes several mathematical constants and methods.
- Math is not a constructor. All properties/methods of Math can be called by using Math as an object, without creating it.
- Note that all trigonometric methods of Math take arguments in radians.

```
var pi_value=Math.PI;
var sqrt_value=Math.sqrt(16);
```

146

## Built-in Objects Math

Method	Description
abs(x)	Returns the absolute value of x
acos(x)	Returns the arccosine of x, in radians
asin(x)	Returns the arcsine of x, in radians
atan(x)	Returns the arctangent of x as a numeric value between -PI/2 and PI/2 radians
atan2(y,x)	Returns the arctangent of the quotient of its arguments
ceil(x)	Returns x, rounded upwards to the nearest integer
cos(x)	Returns the cosine of x (x is in radians)
exp(x)	Returns the value of E <sup>x</sup>

148

## Built-in Objects Number

- The Number object is an object wrapper for primitive numeric values.
- The Number object has properties for numerical constants, such as maximum value, not-a-number, and infinity. You cannot change the values of these properties and you use them as follows:
 

```
biggestNum = Number.MAX_VALUE
smallestNum = Number.MIN_VALUE
```
- Typically, you create a Number object when you want to add some properties to them through the prototype property

```
var num = new Number(value);
Number.prototype.newproperty=value
```

150

## Built-in Objects Number

Property	Description
constructor	Returns the function that created the Number object's prototype
MAX_VALUE	Returns the largest number possible in JavaScript
MIN_VALUE	Returns the smallest number possible in JavaScript
NEGATIVE_INFINITY	Represents negative infinity (returned on overflow)
POSITIVE_INFINITY	Represents infinity (returned on overflow)
prototype	Allows you to add properties and methods to an object

151

## Built-in Objects Number

```
<script type="text/javascript">
    var num = new Number(13.3714);
    document.write(Number.MAX_VALUE+"<br>");
    document.write(Number.MIN_VALUE+"<br>");
    document.write(num.toExponential(4)+"<br>");
    document.write(num.toFixed(2)+"<br>");
    document.write(num.toPrecision(3)+"<br>");
    document.write(num.toString()+"<br>");
    document.write(num.valueOf());
</script>
```

153

## Built-in Objects String

- You can also use the String.length property with a string literal.
- A String object has two types of methods:
  - those that return a variation on the string itself, such as substring and toUpperCase,
  - those that return an HTML-formatted version of the string, such as bold and link.

155

## Built-in Objects Number

Method	Description
	Converts a number into an exponential notation <code>number.toExponential(x)</code>
toExponential(x)	x Optional. An integer between 0 and 20 representing the number of digits in the notation after the decimal point. If omitted, it is set to as many digits as necessary to represent the value
	Formats a number with x numbers of digits after the decimal point <code>number.toFixed(x)</code>
toFixed(x)	x Optional. The number of digits after the decimal point. Default is 0 (no digits after the decimal point)
	Formats a number to x length <code>number.toPrecision(x)</code>
toPrecision(x)	x Optional. The number of digits. If omitted, it returns the entire number (without any formatting)
toString()	Converts a Number object to a string
valueOf()	Returns the primitive value of a Number object

152

## Built-in Objects String

- The String object is a wrapper around the string primitive data type. Do not confuse a string literal with the String object.
- String objects are created with `new String()`.
  - s1 = "Hi" //creates a string literal value
  - s2 = new String("Hi") //creates a String object
- You can call any of the methods of the String object on a string literal value
  - JavaScript automatically converts the string literal to a temporary String object, calls the method, then discards the temporary String object.

154

## Built-in Objects String

Method	Description
charAt()	Returns the character at the specified index
charCodeAt()	Returns the Unicode of the character at the specified index
concat()	Joins two or more strings, and returns a copy of the joined strings <code>String.concat(string2, string3, ..., stringX)</code>
fromCharCode()	Converts Unicode values to characters
indexOf()	Returns the position of the first found occurrence of a specified value in a string
lastIndexOf()	Returns the position of the last found occurrence of a specified value in a string (-1 if the value to search for never occurs) <code>string.lastIndexOf(searchstring, start)</code>
	searchstring Required. The string to search for Start Optional. The start position in the string to start the search. If omitted, the search starts from position 0

156

## Built-in Objects String

Method	Description
<code>match()</code>	Searches for a match between a regular expression and a string, and returns the matches <code>string.match(regex)</code> <code>regexp</code> Required. A regular expression.
<code>replace()</code>	Searches for a match between a substring (or regular expression) and a string, and replaces the matched substring with a new substring <code>string.replace(regex/substr,newstring)</code> <code>regexp/substr</code> Required. A substring or a regular expression. <code>newstring</code> Required. The string to replace the found value in parameter 1
<code>search()</code>	Searches for a match between a regular expression and a string, and returns the position of the match

157

## Built-in Objects String

Method	Description
<code>substr()</code>	Extracts the characters from a string, beginning at a specified start position, and through the specified number of character
<code>substring()</code>	Extracts the characters from a string, between two specified indices
<code>toLowerCase()</code>	Converts a string to lowercase letters
<code>toUpperCase()</code>	Converts a string to uppercase letters
<code>valueOf()</code>	Returns the primitive value of a String object

159

## JavaScript RegExp

- A **regular expression** is an **object** that describes a pattern of characters.
  - A simple pattern can be one single character.
  - A more complicated pattern can consist of more characters, and can be used for parsing, format checking, substitution and more.

- Regular expressions are used to perform powerful pattern-matching and "search-and-replace" functions on text.

```
var txt=new RegExp(pattern,modifiers);
or more simply
var txt=/pattern/modifiers;
```

**pattern** specifies the pattern of an expression  
**modifiers** specify if a search should be global, case-sensitive, etc.

161

## Built-in Objects String

Method	Description
<code>slice()</code>	Extracts a part of a string and returns a new string <code>string.slice(begin,end)</code> <code>begin</code> Required. The index where to begin the extraction. First character is at index 0 <code>end</code> Optional. Where to end the extraction. If omitted, slice() selects all characters from the begin position to the end of the string
<code>split()</code>	Splits a string into an array of substrings <code>string.split(separator, limit)</code> <code>separator</code> Optional. Specifies the character to use for splitting the string. If omitted, the entire string will be returned <code>limit</code> Optional. An integer that specifies the number of splits

158

## Built-in Objects String

```
<script type="text/javascript">
<!-- HTML comment
var str="Hello world!";
document.write(str +<br>);
document.write(str.substring(1) +<br>);
document.write(str.substring(3,7)+<br>);
document.write(str.split('o',2)+"<br>");
document.write(str.toUpperCase()+"<br>");
document.write(str.toLowerCase());
-->
</script>
```

160

## Built-in Objects RegExp

Modifier	Description
<code>i</code>	Perform case-insensitive matching
<code>g</code>	Perform a global match (find all matches rather than stopping after the first match)
<code>m</code>	Perform multiline matching

Method	Description
<code>exec()</code>	Tests for a match in a string. Returns the first match <code>regexp.exec(str)</code> <code>regexp(str)</code>
<code>test()</code>	Tests for a match in a string. Returns true or false <code>regexp.test(str)</code>

162

## Built-in Objects

### RegExp

Expression	Description
[abc]	Find any character between the brackets
[^abc]	Find any character not between the brackets
[0-9]	Find any digit from 0 to 9
[a-z]	Find any character from lowercase a to lowercase z
[A-Z]	Find any character from uppercase A to uppercase Z
[a-Z]	Find any character from lowercase a to uppercase Z
adgk	Find the sequence of characters
(red blue green)	Find any of the alternatives specified

163

## Built-in Objects

### RegExp

Metachar	Description
\0	Find a NUL character
\n	Find a new line character
\f	Find a form feed character
\r	Find a carriage return character
\t	Find a tab character
\v	Find a vertical tab character
\xxx	Find the character specified by an octal number xxx
\xdd	Find the character specified by a hexadecimal number dd
\xxxxx	Find the Unicode character specified by a hexadecimal number xxxx

165

## Built-in Objects

### RegExp

```
<script type="text/javascript">
  var str="100, 1000 or 10000?";
  var patt1=/\d{3,4}/g;
  document.write(str.match(patt1));
</script>
```

Output:

100,1000,1000

167

## Built-in Objects

### RegExp

Metachar	Description
.	Find a single character, except newline or line terminator
\w	Find a word character
\W	Find a non-word character
\d	Find a digit
\D	Find a non-digit character
\s	Find a whitespace character
\S	Find a non-whitespace character
\b	Find a match at the beginning/end of a word
\B	Find a match not at the beginning/end of a word

164

## Built-in Objects

### RegExp

Quantifier	Description
n+	Matches any string that contains at least one n
n*	Matches any string that contains zero or more occurrences of n
n?	Matches any string that contains zero or one occurrences of n
n{X}	Matches any string that contains a sequence of X n's
n{X,Y}	Matches any string that contains a sequence of X or Y n's
n{X,}	Matches any string that contains a sequence of at least X n's
n\$	Matches any string with n at the end of it
^n	Matches any string with n at the beginning of it
?=n	Matches any string that is followed by a specific string n
?!=n	Matches any string that is not followed by a specific string n

166

## Built-in Objects

### Global Properties and Functions

- The JavaScript global properties and functions can be used with all the built-in JavaScript objects.

Property	Description
Infinity	A numeric value that represents positive/negative infinity
NaN	"Not-a-Number" value
undefined	Indicates that a variable has not been assigned a value

Function	Description
decodeURI()	Decodes a URI
decodeURIComponent()	Decodes a URI component
encodeURI()	Encodes a URI
encodeURIComponent()	Encodes a URI component

168

## Built-in Objects Global Properties and Functions

Function	Description
<code>escape()</code>	Encodes a string
<code>eval()</code>	Evaluates a string and executes it as if it was script code. First, <code>eval()</code> determines if the argument is a valid string, then <code>eval()</code> parses the string looking for JavaScript code. If it finds any JavaScript code, it will be executed.
<code>isFinite()</code>	Determines whether a value is a finite, legal number
<code>isNaN()</code>	Determines whether a value is an illegal number
<code>Number()</code>	Converts an object's value to a number
<code>parseFloat()</code>	Parses a string and returns a floating point number
<code>parseInt()</code>	Parses a string and returns an integer
<code>String()</code>	Converts an object's value to a string
<code>unescape()</code>	Decodes an encoded string

169

## Client-side Objects

### Client-side objects Objects in a Page

Every page has the following objects

- **navigator:** has properties for the name and version of the Navigator being used, for the MIME types supported by the client, and for the plugins installed on the client.
- **window:** the top-level object; has properties that apply to the entire window. There is also a `window` object for each "child window" in a frames document.
- **document:** contains properties based on the content of the document, such as title, background color, links and forms.
- **location:** has properties based on the current URL.
- **history:** contains properties representing URLs the client has previously requested.

173

## Built-in Objects Global Properties and Functions

```
<script type="text/javascript">
  eval("x=10;y=20;document.write(x*y)");
  document.write("<br>" + eval("2+2"));
  document.write("<br>" + eval(x+17));
</script>
```

Output:

200

4

27

170

## Client-side objects

When you load a document in a Browser, it creates a number of JavaScript Objects.

### Client-side objects Controlling objects

By controlling Objects, we can

- **Open new browser windows**, and determine their size and whether they should have scroll bars, or location windows
- **Change the content of multiple frames at once**, even rewriting the HTML in a frame without downloading a new file
- **Add or remove text from forms** including text areas and select boxes
- **Control the background color of your Web pages** using JavaScript
- etc...

## Client-side objects

### Window Object

- Every browser window that is currently open will have a corresponding **window Object**.
- If a document contain frames (<frame> or <iframe> tags), the browser creates one window object for the HTML document, and one additional window object for each frame.
- All the other Objects are children of one of the window Objects, except for navigator and screen.

175

## Client-side objects

### Window Object Properties

Property	Description
<code>closed</code>	Returns a Boolean value indicating whether a window has been closed or not
<code>defaultStatus</code>	Sets or returns the default text in the statusbar of a window
<code>document</code>	Returns the Document object for the window
<code>frames</code>	Returns an array of all the frames (including iframes) in the current window
<code>history</code>	Returns the History object for the window
<code>innerHeight</code>	Sets or returns the inner height of a window's content area
<code>innerWidth</code>	Sets or returns the inner width of a window's content area
<code>length</code>	Returns the number of frames (including iframes) in a window

177

## Client-side objects

### Window Object Properties

Property	Description
<code>parent</code>	Returns the parent window of the current window
<code>screen</code>	Returns the Screen object for the window
<code>screenLeft</code>	Returns the x coordinate of the upper-left hand corner of the window (Explorer – Opera)
<code>screenTop</code>	Returns the y coordinate of the upper-left hand corner of the window (Explorer – Opera)
<code>screenX</code>	Returns the x coordinate of the upper-left hand corner of the window (Firefox – Chrome)
<code>screenY</code>	Returns the y coordinate of the upper-left hand corner of the window (Firefox – Chrome)
<code>self</code>	Returns the current window
<code>status</code>	Sets the text in the statusbar of a window
<code>top</code>	Returns the topmost browser window

179

## Client-side objects

### Window Object

- Every window **has a history of the previous pages** that have been displayed in that window, which are represented by the various properties of the history object.
- JavaScript maintains an idea of the current window**, so that almost all references to sub-objects of the current window do not need to refer to it explicitly.
  - This is why all of our output has been done using `document.write()` rather than `window.document.write()`.

176

## Client-side objects

### Window Object Properties

Property	Description
<code>location</code>	Returns the Location object for the window
<code>name</code>	Sets or returns the name of a window
<code>navigator</code>	Returns the Navigator object for the window
<code>opener</code>	Returns a reference to the window that created the window
<code>outerHeight</code>	Sets or returns the outer height of a window, including toolbars/scrollbars
<code>outerWidth</code>	Sets or returns the outer width of a window, including toolbars/scrollbars
<code>pageXOffset</code>	Returns the pixels the current document has been scrolled (horizontally) from the upper left corner of the window
<code>pageYOffset</code>	Returns the pixels the current document has been scrolled (vertically) from the upper left corner of the window

178

## Client-side objects

### Window Object Properties

Method	Description
<code>alert()</code>	Displays an alert box with a message and an OK button
<code>blur()</code>	Removes focus from the current window
<code>clearInterval()</code>	Clears a timer set with <code>setInterval()</code>
<code>clearTimeout()</code>	Clears a timer set with <code>setTimeout()</code>
<code>close()</code>	Closes the current window
<code>confirm()</code>	Displays a dialog box with a message and an OK and a Cancel button
<code>focus()</code>	Sets focus to the current window

180

## Client-side objects

### Window Object Methods

Method	Description
<code>moveBy()</code>	Moves a window relative to its current position
<code>moveTo()</code>	Moves a window to the specified position
<code>open()</code>	Opens a new browser window
<code>print()</code>	Prints the content of the current window
<code>prompt()</code>	Displays a dialog box that prompts the visitor for input
<code>resizeBy()</code>	Resizes the window by the specified pixels
<code>resizeTo()</code>	Resizes the window to the specified width and height

181

## Client-side objects

### Window Object Methods

```
<title>Example</title>
<script type="text/javascript">
    var myWindow;
    function openWin()
    {
        myWindow=window.open("",'width=200,height=100');
        myWindow.document.write("This is 'myWindow'");
    }

    function closeWin()
    {
        myWindow.close();
    }

    function moveWin()
    {
        myWindow.moveBy(250,250);
        myWindow.focus();
    }
</script>
</head>
```

183

## Client-side objects

### Navigator Object

- The **navigator object** contains information about the browser.
- The JavaScript runtime engine on the client automatically creates the navigator object.
- Use the navigator object to determine **which version** of the Navigator your users have, **what MIME types** the user's Navigator can handle, and **what plugins** the user has installed.
- All of the properties of the navigator object are **read-only**.

185

## Client-side objects

### Window Object Methods

Method	Description
<code>scrollBy()</code>	Scrolls the content by the specified number of pixels
<code>scrollTo()</code>	Scrolls the content to the specified coordinates
<code>setInterval()</code>	Calls a function or evaluates an expression at specified intervals (in milliseconds)
<code>setTimeout()</code>	Calls a function or evaluates an expression after a specified number of milliseconds

182

## Client-side objects

### Window Object Methods

```
<body>
<div>
    <input type="button" value="Open 'myWindow'" onclick="openWin()">
    <br><br>
    <input type="button" value="Move 'myWindow'" onclick="moveWin()">
    <br><br>
    <input type="button" value="Close 'myWindow'" onclick="closeWin()">
</div>
</body>
</html>
```

184

## Client-side objects

### Navigator Object

Property	Description
<code>appCodeName</code>	Returns the code name of the browser
<code>appName</code>	Returns the name of the browser
<code>appVersion</code>	Returns the version information of the browser
<code>battery</code>	Returns information about the battery charging status.
<code>cookieEnabled</code>	Determines whether cookies are enabled in the browser
<code>platform</code>	Returns for which platform the browser is compiled
<code>userAgent</code>	Returns the user-agent header sent by the browser to the server

186

## Client-side objects

### Navigator Object (example 1)

```
<script type="text/javascript">
document.write("Code Name: " + navigator.appCodeName +
"<br>");
document.write("Name: " + navigator.appName + "<br> ");
document.write("Platform: " + navigator.platform + "<br> ");
document.write("User Agent: " + navigator.userAgent + "<br> ");
</script>
```

Output:

Code Name: Mozilla  
 Name: Microsoft Internet Explorer  
 Platform: Win32  
 User Agent: Mozilla/4.0 (compatible; MSIE 8.0; Windows NT 5.1;  
 Trident/4.0; GTB6.5; .NET CLR 1.1.4322; .NET CLR 2.0.50727;  
 .NET CLR 3.0.4506.2152; .NET CLR 3.5.30729)

187

## Client-side objects

### Navigator Object (example 2)

**Information on your browser**

**appCodeName:**Mozilla  
**appName:**Microsoft Internet Explorer  
**appMinorVersion:**0  
**cpuClass:**x86  
**platform:**Win32  
**plugins:**[object]  
**opsProfile:**null  
**userProfile:**null  
**systemLanguage:**en-us  
**userLanguage:**it  
**appVersion:**4.0 (compatible; MSIE 7.0; Windows NT 5.1; Trident/4.0; GTB6.5; .NET CLR 1.1.4322; .NET CLR 2.0.50727; .NET CLR 3.0.4506.2152; .NET CLR 3.5.30729)  
**userAgent:**Mozilla/4.0 (compatible; MSIE 7.0; Windows NT 5.1; Trident/4.0; GTB6.5; .NET CLR 1.1.4322; .NET CLR 2.0.50727; .NET CLR 3.0.4506.2152; .NET CLR 3.5.30729)  
**onLine:**true  
**cookieEnabled:**true  
**mimeType:**

189

## Client-side objects

### Screen Object (example)

```
//myscript6.js
document.writeln("<h1>Screen Information</h1><p>"); 
printScreenInfo('width'); printScreenInfo('height');
printScreenInfo('colorDepth'); printScreenInfo('availWidth');
printScreenInfo('availHeight');

function printScreenInfo(name) {
document.writeln("<strong>" + name + ":</strong>" +
screen[name] + "<br>"); 
}

Output:
width:1680
height:1050
colorDepth:32
availWidth:1680
availHeight:1016
```

191

## Client-side objects

### Navigator Object (example 2)

```
\myscript5.js
var infobrowser = "<h1>Information on your browser</h1><p>";
for (var propName in navigator)
  infobrowser += "<strong>" + propName + "</strong>" +
  navigator[propName] + "<br>";
  infobrowser += "</p>";
  document.writeln(infobrowser);
if (navigator.appName.indexOf("Netscape") != -1)
  window.alert("Your browser is Netscape");
else if (navigator.appName.indexOf("Microsoft Internet Explorer") != -1)
  window.alert("Your browser is Internet Explorer");
```

188

## Client-side objects

### Screen Object

- Contains read-only properties describing the display screen and colours.

Property	Description
availHeight	Returns the height of the screen (excluding the Windows Taskbar)
availWidth	Returns the width of the screen (excluding the Windows Taskbar)
colorDepth	Returns the bit depth of the color palette for displaying images (the $\log_2$ of the number of colors)
height	Returns the total height of the screen
pixelDepth	Returns the color resolution (in bits per pixel) of the screen
width	Returns the total width of the screen

190

## Client-side objects

### History Object (properties)

- The history object contains the URLs visited by the user (within a browser window).
- The history object is part of the window object and is accessed through the window.history property

**length** – contains the current length of the history list

- The history Object does not contain any values that reflect the actual URLs in the history list.
- Therefore, you cannot, for example, perform some action that reads the value of "URL number 3 in the history list"
- The history Object is designed for navigating the history list.

192

## Client-side objects

### History Object (Methods)

- **back()** – moves the user to the URL one place previous in the history list (previous to the current position).
- **forward()** - moves the user one URL forward, relative to current position, in the history list
- **go(offset)** - accepts an integer parameter, positive or negative, as offset.
  - If the parameter is a positive integer, the program will move the user that many places forward in the history list.
  - If the parameter is negative, it'll move the user that many places backward (previous to the current position) in the history list.
  - The current position is always place zero.
- **go(substring)** - searches for the newest history list URL that contains the specified string somewhere within its URL string
  - `history.go("email.htm");`

193

## Client-side objects

### Location Object (properties)

- The location Object contains information on the current URL.
- **href** - contains the string value of the entire URL
    - `window.open(location.href, "windowName", "feature1,feature2, ...");`
    - open a new window, which connects to the same URL as the current window (so you can look at another portion of the same page at the same time you're looking at the current portion of the page)
    - `location.href = "http://www.someISP.com/~me/myPage.htm";`
    - Launch a new page without opening a new window (you leave your current page, including other JavaScript programs).

195

## Client-side objects

### Location Object (properties)

- **hostname** – returns the hostname portion of the URL.
  - **pathname** - is the portion of the URL that describes the location of the Web document on the host computer.
    - Example:
   
`http://www.someISP.com/~me/myPage.htm`
  
`location.pathname -> ~/me/myPage.htm`
- Assigning a value to this property,
- `location.pathname = "~me/otherdocs/newdoc.htm";`
- will cause the Web browser to load that document into the current window.

197

## Client-side objects

### History Object (Example)

```
<body>
<div>
  Go to the page:<br>
  <button onclick="history.go(-1);">Back</button>
  <button onclick="history.go(0);">Current</button>
  <button onclick="history.go(+1);">Forward</button>
</div>
```

194

## Client-side objects

### Location Object (properties)

- **host** - holds only the hostname and port of the current page's URL
  - Example:
   
`http://www.someISP.com:80/~me/myPage.htm`
  
`location.host -> " www.someISP.com:80"`
  - Note: Assigning a value to location.host will generate an error because it is nonsensical. Whereas you can assign an entire URL to location.href, which would then connect to that URL.  
You cannot connect to just a host.
- **port** - contains the value of the port number in the URL

196

## Client-side objects

### Location Object (properties)

- **protocol** – contains the leftmost portion of the URL.
  - By checking the location.protocol property, the JavaScript program can determine if the page currently resides in was delivered by HTTP, FTP, or NEWS.
- **hash** – contains the value following the hash mark
  - Some URLs contain special hash mark values following the pathname.
   
`http://www.someISP.com/~me/myPage.htm#item1`
  
The hash mark (#) specifies the name of an anchor to jump to in the Web page.
   
`location.hash -> item1`
  - You can use the location.hash property in Event Handlers to bring the user to specific locations within the current page.

198

## Client-side objects

### Location Object (properties)

- **search** – contains the value following the question mark.
  - Some URLs contain search parameters following the pathname, denoted with a question mark (?).
  - A form entry is probably the most common use for a search parameter.
- http://www.someISP.com/~me/myProgram?formData
- location.search -> formData
- **reload()** – reloads the document that is currently displayed in the window of the location Object.
- **assign(newURL)** – loads a new document.
- **replace(newURL)** – replaces the current document with a new one.

199

## Client-side objects

### Location Object (example)

```
//myscript7.js
display('URL',location.href);
display('Protocol',location.protocol);
display('Host name', location.hostname);
display('Local Address', location.hash);
display('Port', location.port);
display('Path', location.pathname);

function send() {
location.search = "&Name=" + document.forms[0].Name.value;

}

function display(propriety, value) {
document.writeln("<p><strong>" + propriety + ":" + value + "</strong>" + "</p>");
}
```

201

## Client-side objects

### Document Object Collections (DOM 0)

## Client-side objects

### Location Object (example)

```
<html>
<head>
<title> Location Object</title>
<script type="text/javascript" src=".//myscript7.js">
</script>
</head>
<body>
<form action="#" method="get">
<p><strong>Insert your name:</strong><br>
<input type="text" name="Name">
<input type="button" onclick= "send()" value="SEND"></p>
</form>
</body>
</html>
```

200

## Client-side objects

### Document Object

- Each **HTML document loaded into a browser window becomes a Document object.**
- The Document object provides access to all HTML elements in a page, from within a script.
- Tip: **The Document object is also part of the Window object**, and can be accessed through the `window.document` property
- A document is the file of HTML codes that describe a given page.
  - A page is what appears within the browser window. So, every window is associated with a document object.

202

## Client-side objects

### Document Object (Properties)

Property	Description
<code>activeElement</code>	Returns the currently focused element.
<code>body</code>	Returns the <code>&lt;body&gt;</code> element of the current document.
<code>cookie</code>	Returns a semicolon-separated list of the cookies for that document or sets a single cookie.
<code>defaultView</code>	Returns a reference to the window object.
<code>dir</code>	Gets/sets directionality (rtl/ltr) of the document.
<code>domain</code>	Specifies the domain name of the server that served a document
<code>head</code>	Returns the <code>&lt;head&gt;</code> element of the document.
<code>lastModified</code>	Returns the date on which the document was last modified.
<code>location</code>	Returns the URI of the current document.

204

## Client-side objects

### Document Object (Properties)

Property	Description
plugins	Returns a list of the available plugins.
readyState	Returns loading status of the document.
referrer	Returns the URI of the page that linked to this page.
title	Returns the title of the current document.
URL	Returns a string containing the URL of the current document.

- Note: document.URL property may be modified through URL redirection. Thus, location.href contains the requested URL while document.URL specifies the actual URL where it was found.

205

## Client-side objects

### Document Object (Methods)

- Note: How is it possible to change the presentation style of the elements?
- Use the "style" property.
- Note: the names of the properties do not have hyphens and are in camelCase notation.
- For instance:
  - background-color -> backgroundColor
  - border-right-style -> borderRightStyle
- Example
 

```
element.style.backgroundColor = 'yellow'
```

207

## Client-side objects

### Document Object (Methods)

- Note: write() method actually takes a variable number of arguments, rather than just one.
  - If more than one argument is given, each of the arguments is interpreted as a string and written in turn.
- document.write("This is Part 1 ", "and this is Part 2 ", "and this is Part 3");
- Note: writeln() appends a newline character to the end of the output.
  - Keep in mind that these methods output their parameters as HTML. HTML ignores newline characters when it comes to outputting to the screen. HTML does not insert line breaks in screen output unless you specify a line break using either <br> or <p> tags or text resides between <pre> and </pre> tags.

209

## Client-side objects

### Document Object (Methods)

Method	Description
close()	Closes the output stream previously opened with document.open()
open()	Opens an output stream to collect the output from document.write() or document.writeln()
write()	Writes HTML expressions or JavaScript code to a document
writeln()	Same as write(), but adds a newline character after each statement

- Note: document.URL property may be modified through URL redirection. Thus, location.href contains the requested URL while document.URL specifies the actual URL where it was found.

206

## Client-side objects

### Document Object (Methods)

- write(str) – outputs text to the client window's document
  - document.write() "converts" everything to HTML
  - the browser then interprets the HTML and then renders the HTML
- writeln(str) – outputs text to the client window's document (appends a newline character to the end of the output)
  - str - strings of text are surrounded by double (or single) quotes

#### Examples:

```
document.write("<h1>Thank you for ordering!</h1>");  
document.write(example);  
where example is a string variable
```

208

## Client-side objects

### Document Object (Methods)

- Note: write() method actually takes a variable number of arguments, rather than just one.
  - If more than one argument is given, each of the arguments is interpreted as a string and written in turn.
- document.write("This is Part 1 ", "and this is Part 2 ", "and this is Part 3");
- Note: writeln() appends a newline character to the end of the output.
  - Keep in mind that these methods output their parameters as HTML. HTML ignores newline characters when it comes to outputting to the screen. HTML does not insert line breaks in screen output unless you specify a line break using either <br> or <p> tags or text resides between <pre> and </pre> tags.

209

## Client-side objects

### Document Object (Example)

```
<body> <p>  
  <a href="#"  
    onclick="openW('yellow')>open yellow window</a><br>  
  <a href="#"  
    onclick="openW('red')>open red window</a><br>  
  <a href="#"  
    onclick="openW('blue')>open blue window</a>  
</p><p>  
  <a href="#"  
    onclick="openDoc('yellow')>open yellow page</a><br>  
  <a href="#"  
    onclick="openDoc('red')>open red page</a><br>  
  <a href="#"  
    onclick="openDoc('blue')>open blue page</a>  
</p> </body>
```

210

## Client-side objects

### Document Object (Example)

```
document.writeln("<p>You are on " + document.URL + "</p>");
function openW(color) {
    win = window.open("",color,"width=400,height=250");
    HTMLcode = '<html><head><meta charset="utf-8"><title>Page ' + color+ '</title></head>' +
    '<body><p>This is a ' + color + ' page </p></body></html>';
    win.document.writeln(HTMLcode);
    win.document.body.style.backgroundColor = color;
    win.document.body.style.color = "white";
}
```

211

## Client-side objects

### Document Object (Methods)

#### Double and Single Quotes

- When writing **HTML** it is **general practice** to use **double quotes** for tag attributes, e.g.:
- ```

```
- When writing **JavaScript** it is **general practice** to use **single quotes** for string literals:

```
<script type="text/javascript">
    document.write('<p>');
</script>
```

In general these quoting styles then complement one another when outputting HTML using JavaScript

213

## Client-side objects

### How are objects named? (DOM 0)

**Leave off the word "window."**

- All Client-side Object names officially start with the highest Object name, "window". But since all names start with "window", JavaScript allows you to leave that off.

- document.forms[0].elements[3]

215

## Client-side objects

### Document Object (Example)

```
function openDoc(color) {
    doc = document.open("text/html","replace");
    HTMLcode = '<html><head><meta charset="utf-8"><title>Page ' + color+ '</title></head>' +
    '<body><p>This is a ' + color + ' page </p></body></html>';
    doc.writeln(HTMLcode);
    doc.body.style.backgroundColor = color;
    doc.body.style.color = "green";
    doc.close();
}
```

212

## Client-side objects

### How are objects named? (DOM 0)

- You can access only to a subset of all elements contained in a document, through the document object.
- The **name of each Object** is prefaced by the **names of all the Objects** that contain it, in order, separated by dots.
- For example, the **window Object** contains the **document Object**, and the **document Object** contains a **form Object**, and the **form Object** contains **text input fields, buttons, select Objects, etc...** — **window.document.forms[0].elements[3]**

214

## Client-side objects

### How are objects named? (DOM 0)

#### Form elements

- The numerous Object types included in the Forms Array are collectively referred to as "elements" and they can all be referred to by means of the "Elements Array" (e.g.: elements[1]).
- Example: **document.forms[0].elements[1]**

216

## Client-side objects

### How to refer to properties or methods?

- Note: JavaScript is case sensitive
  - document.myform.Check1 is not the same "Object" as document.myform.check1
- The form Object has child objects named button1 and text1, corresponding to the button and text field in the form.
- These objects have their own properties based on their HTML attribute values, for example,
  - document.myform.button1.value is "Press Me"
  - document.myform.elements[2].name is "Button1"
  - document.myform.elements[0].name is "text1"

217

## Client-side objects

### How to refer to properties or methods?

```
<title>A Simple Document</title>
</head>
<body>
<p><a name="top" id="top">This is the top of the page</a><p>
<hr>
<form method="post" action="%20mailto:nobody@dev.null">
<p>Enter your name: <input type="text" name="me" size="70">
<input type="Submit" value="OK">
<input type="Reset" value="Oops"></p>
</form>
<hr>
<p>Click here to go to the <a href="#top">top</a> of the
page</p>
</body>
</html>
```

219

## Client-side objects

### How to refer to properties or methods?

**document.title**  
<title>A very simple HTML page</title>  
**document.anchors[0]**  
<a name="top">This is the top of the page</a>  
**document.anchors[0].name** -> top

**document.forms[0]**  
<form method="post" action="mailto:nobody@dev.null">  
**document.forms[0].method** -> post  
**document.forms[0].action** -> mailto:nobody@dev.null

221

## Client-side objects

### How to refer to properties or methods?

- Three different ways to specify the value of an object:
  - document.myform.text1.value is "blahblah"
 **NOTE:** using just the object names
  - document.myform.elements[0].value is "blahblah"
 **NOTE:** using an object name & array notation (to specify the object instead of the object name)
  - document.forms[0].elements[0].value is "blahblah"
 **NOTE:** using just array notation

218

## Client-side objects

### How to refer to properties or methods?

- The code creates an HTML page with an anchor at the top of the page and a link to that anchor at the bottom.
- In between is a simple form that allows the user to enter his name.
- We can also access the other HTML elements of this document using the following properties:
  - anchors
  - forms
  - links

220

## Client-side objects

### How to refer to properties or methods?

**document.forms[0].elements[0]**  
<input type="text" name="me" size="70">  
**document.forms[0].elements[0].name** -> me  
**document.forms[0].elements[0].type** -> text

**document.forms[0].elements[1]**  
<input type="Submit" value="OK">  
**document.forms[0].elements[1].value** -> OK  
**document.forms[0].elements[1].type** -> Submit

**document.forms[0].elements[2]**  
<input type="Reset" value="Oops">  
**document.forms[0].elements[2].value** -> Oops  
**document.forms[0].elements[2].type** -> Reset

222

## Client-side objects

### How to refer to properties or methods?

`document.links[0]`

`<a href="#top">top</a>`

`document.links[0].href`

`file:///F:/Examples/example1.htm#top`

223

## Document Object Model

### DOM

- "The W3C Document Object Model (DOM) is a platform and language-neutral interface that allows programs and scripts to dynamically access and update the content, structure, and style of a document."
- The DOM is separated into 3 different parts / levels:
  - Core DOM - standard model for any structured document
  - XML DOM - standard model for XML documents
  - HTML DOM - standard model for HTML documents
- The DOM defines the objects and properties of all document elements, and the methods (interface) to access them.

225

## DOM

The HTML DOM is:

- A standard object model for accessing and manipulating HTML documents HTML
  - A standard programming interface for HTML
  - Platform- and language-independent
  - A W3C standard
- In other words: The HTML DOM is a standard for how to get, change, add, or delete HTML elements.

227

## Client-side objects

### Document

- Each object in the document has specific properties and methods.
- The access to each element using the approach described so far is not flexible, is limited and does not allow changing dynamically the structure of the document.
- The ability to change a Web page dynamically with a scripting language is made possible by the Document Object Model (DOM), which can connect any element on the screen to a JavaScript function.

224

## Document Object Model

### DOM

```
<!DOCTYPE html>
<html>
<head>
<title>Sample page</title>
</head>
<body>
<h1>Sample page</h1>
<p>This is a <a href="demo.html">simple</a>
sample.</p>
<!-- this is a comment -->
</body>
</html>
```

226

## DOM

- According to the DOM, everything in an HTML document is a node.
  - The entire document is a document node
  - Every HTML element is an element node
  - The text in the HTML elements are text nodes
  - Every HTML attribute is an attribute node
  - Comments are comment nodes

228

## DOM

```
<html>
  <head> <title>DOM Tutorial</title> </head>
  <body>
    <h1>DOM Lesson one</h1>
    <p>Hello world!</p>
  </body>
</html>
```

- The **root node** in the HTML above is `<html>`. All other nodes in the document are contained within `<html>`.
- The `<html>` node has **two child nodes**: `<head>` and `<body>`.
- The `<head>` node holds a `<title>` node. The `<body>` node holds a `<h1>` and `<p>` nodes.

229

## DOM Tree

- The HTML DOM views a HTML document as a tree-structure. The tree structure is called a **node-tree**.
- All nodes can be accessed through the tree.

231

## DOM Tree

- `<head>` element: first child of the `<html>` element
- `<body>` element: last child of the `<html>` element
- `<h1>` element: first child of the `<body>` element
- `<p>` element: last child of the `<body>` element
- The programming interface of the DOM is defined by standard properties and methods.

233

- A common error in DOM processing is to expect an element node to contain text. However, **the text of an element node is stored in a text node**.
- In this example: `<title>DOM Tutorial</title>`, the element node `<title>` holds a text node with the value "DOM Tutorial".
  - "DOM Tutorial" is not the value of the `<title>` element!

230

## DOM Tree

- Parent nodes have children**. Children on the same level are called **siblings** (brothers or sisters).
- Every node, except the root, has exactly one parent node

232

## DOM (Level 3) Tree

- Some attributes:
  - `x.innerHTML` - the text value of x (**not a part of the W3C DOM specification, but supported by all major browsers**)  
YOU MUST NOT USE INNERHTML
  - `x.childNodes` - the child nodes of x
  - `x.parentNode` - the parent of x
  - `x.firstChild` – the first child of x
  - `x.lastChild` – the last child of x
  - `x.localName` – the local part of the qualified name of x
  - `x.namespaceURI` – the namespace URI of this node of x
  - `x.nodeName` - the name of x
  - `x.nodeValue` - the value of x
  - `x.nodeType` – the type of x
- Note: In the list above, x is a node object (HTML element).

234

## DOM (Level 3) Tree

- Some attributes:
  - `x.nextSibling` – next brother of x
  - `x.previousSibling` – previous brother of x
  - `x.textContent` – returns the text content of x and its descendants
  - `x.attributes` - the attributes nodes of x
- Note: In the list above, x is a node object (HTML element).

235

## DOM (Level 3) Tree

As specified by the DOM API, each HTML element is represented by an object, hence the term "Object Model".

237

## DOM (Level 3) Tree (Methods)

- `x.replaceChild(newC,oldC)` - replaces oldC with newC and returns oldC
- `x.hasChildNodes()` – returns true if the object has sons; false otherwise
- `x.contains(node)` - returns a Boolean value indicating whether a node is a descendant of x or not
- `x.isEqualNode(node)` – tests whether x is equal to node
- `x.lookupNamespaceURI()` - takes a prefix and returns the namespace URI associated with it on the given node if found (and null if not).

239

## DOM (Level 3) Tree

- `myNode.nodeType == Node.ELEMENT_NODE`  
myNode is an object Element
- `myNode.nodeType == Node.ATTRIBUTE_NODE`  
Node is an attribute

Main types of nodes:

```

const unsigned short ELEMENT_NODE = 1
const unsigned short ATTRIBUTE_NODE = 2
const unsigned short TEXT_NODE = 3
const unsigned short ENTITY_NODE = 6 (XML documents)
const unsigned short PROCESSING_INSTRUCTION_NODE = 7
const unsigned short COMMENT_NODE = 8
const unsigned short DOCUMENT_NODE = 9
  
```

236

## DOM (Level 3) Tree (Methods)

- `x.getElementById(id)` - gets the element with a specified id
- `x.getElementsByTagName(name)` - gets all elements with a specified tag name
- `x.appendChild(node)` - adds a child node to the end of the list of children of x
- `x.compareDocumentPosition(node)` – compares x with the node passed as a parameter, with regard to their position in the document and according to the document order. Returns a short integer which denotes how the node is positioned relatively to x.
- `newx = x.cloneNode(deep)` – clones x to create a new object: if deep == true, all the tree with x as root is cloned; otherwise only node x
- `x.removeChild(node)` - removes a child node from x and returns it

238

## DOM (Level 3) Tree (Methods)

- Read and set the attributes of elements
- `x.getAttribute(string_name)` – returns the value of the attribute string\_attribute
  - `x.setAttribute(string_name, string_value)` – set the value of the attribute string\_name to string\_value

```

function showAttributes() {
  var result;
  var elems = document.getElementsByTagName("input");
  for (var i=0;i<elems.length;i++) {
    result = "";
    for (var a in elems[i]) {
      aValue = elems[i].getAttribute(a);
      if (a=="type") result += "- " + a + ": " + aValue + "\n";
    }
    window.alert("Attributes of " + elems[i].tagName + ":" + result);
  }
}
  
```

240

## DOM Tree (get or modify the content of an element)

- Attention: The easiest way to get or modify the content of an element is by using the innerHTML property, **but it is not W3C**.

Two solutions:

- First Solution: Use the childNodes and NodeValue properties

```
<body>
<p id="intro">Hello World!</p>
...
function change()
{ txt=document.getElementById("intro").childNodes[0].nodeValue;
document.getElementById("intro").childNodes[0].nodeValue="hi";
document.write("<p>The text from the intro paragraph: " + txt +
"</p>");
}
```

241

## DOM Tree (get or modify the content of an element)

- Second Solution: use the firstChild and NodeValue properties

```
function change()
{
txt=document.getElementById("intro").firstChild.nodeValue;
document.getElementById("intro").firstChild.nodeValue="hi";
document.write("<p>The text from the intro paragraph: " + txt +
"</p>");
```

}

242

## DOM Tree (Example)

```
<!DOCTYPE html>
<html>
<head>
<meta charset="utf-8">
<title> Object Model Example </title>
</head>
```

243

## DOM Tree (Example)

245

## DOM Tree (Example)

```
<body id="mybody">
<p id="mypar1">
  An image:
</p>
<ul>
  <li>First
  </li>
  <li>Second
  </li>
</ul>
<script type="text/javascript" src=".//myscript1.js"> </script>
</body>
</html>
```

244

## DOM Tree Access to a node

You can access a node in three ways:

- By using the getElementById() method
- By using the getElementsByTagName() method
- By navigating the node tree, using the node relationships

246

## DOM Tree Access to a node

### 1. Use of the `getElementById` method (myscript1.js)

```
var text =
  document.getElementById("mypar1").firstChild.nodeValue;
window.alert("The paragraph has the text " + text + "!");
var body = document.getElementById("mybody");
var textNode = body.childNodes[0].firstChild;
//Explorer (old versions)
if (!textNode) window.alert("Mozilla Firefox");
else window.alert("Microsoft Explorer");
text = textNode ? textNode.nodeValue :
  body.childNodes[1].firstChild.nodeValue; //Mozilla
window.alert("The paragraph has the text " + text + "!");
```

247

## DOM Tree Access to a node

### 2. Using the `getElementsByTagName` method (file myscript2.js)

```
var elems = document.getElementsByTagName("p");
var text = elems[0].firstChild.nodeValue;
window.alert("The paragraph has the text " + text + "!");
```

249

## DOM Tree Access to a node

### 3. Navigating the DOM tree (example 2 - file myscript4.js)

```
function visit(node,obj)
{ if (node==null) return;
  if (node.firstChild)
  { obj.txt+=node.firstChild.nodeType + "."
    + node.firstChild.nodeName + "=" +
    node.firstChild.nodeValue + "<br>";
    visit(node.firstChild,obj);
  }
  if (node.nextSibling)
  { obj.txt+=node.nextSibling.nodeType + "."
    + node.nextSibling.nodeName + "=" +
    node.nextSibling.nodeValue + "<br>";
    visit(node.nextSibling,obj);}
}
```

251

<p><i>Università di Pisa</i></p> <h2>Events</h2> <ul style="list-style-type: none"> <li>■ Events are actions that can be detected by JavaScript.</li> <li>■ Every element on a web page has certain events which can trigger a JavaScript handler.</li> <li>■ The events are defined in the HTML tags</li> <li>■ Note: events are normally used in combination with functions, and the function will not be executed before the event occurs!             <ul style="list-style-type: none"> <li>■ For example, we can use the onClick event of a button element to indicate that a function will run when a user clicks on the button</li> </ul> </li> </ul>	<p><i>Francesco Marcelleni</i></p>	<p><i>Università di Pisa</i></p>	<p><i>Francesco Marcelleni</i></p>
<p>253</p>	<p>254</p>	<p>254</p>	<p>254</p>
<p><i>Università di Pisa</i></p> <h2>Event Object (Definition)</h2> <p>Example</p> <ul style="list-style-type: none"> <li>■ mouse-down event. The event object contains             <ul style="list-style-type: none"> <li>■ the type of event (in this case MouseDown),</li> <li>■ the x and y position of the cursor at the time of the event,</li> <li>■ a number representing the mouse button used,</li> <li>■ a field containing the modifier keys (Control, Alt, Meta, or Shift) that were depressed at the time of the event.</li> </ul> </li> <li>■ The properties used within the event object vary from one type of event to another.             <ul style="list-style-type: none"> <li>■ This variation is provided in the descriptions of individual event handlers.</li> </ul> </li> </ul>	<p><i>Francesco Marcelleni</i></p>	<p><i>Università di Pisa</i></p>	<p><i>Francesco Marcelleni</i></p> <h2>Event Object (Definition)</h2> <ul style="list-style-type: none"> <li>■ The event object gives you information about an event that has occurred.</li> <li>■ The Event object represents the state of an event, such as the element in which the event occurred, the state of the keyboard keys, the location of the mouse, and the state of the mouse buttons.</li> <li>■ Events are normally used in combination with functions (Event handlers), and the function will not be executed before the event occurs!</li> <li>■ The event object contains properties that describe a JavaScript event, and is passed as an argument to an event handler when the event occurs.</li> </ul>
<p>255</p>	<p>256</p>	<p>256</p>	<p>256</p>
<p><i>Università di Pisa</i></p> <h2>Event Object To Associate Events with Code</h2> <ul style="list-style-type: none"> <li>■ First Approach (example)</li> </ul> <pre>&lt;body&gt;   &lt;div style="position:absolute; left:300px; top:200px;" id="but"&gt;     &lt;button onmouseover="moveMouse()"&gt;Click&lt;/button&gt;   &lt;/div&gt;   &lt;script type="text/javascript" src=".myscript10.js"&gt;   &lt;/script&gt; &lt;/body&gt;</pre>	<p><i>Francesco Marcelleni</i></p>	<p><i>Università di Pisa</i></p>	<p><i>Francesco Marcelleni</i></p> <h2>Event Object To Associate Events with Code</h2> <ul style="list-style-type: none"> <li>■ First approach – Events as HTML element attributes             <ul style="list-style-type: none"> <li>■ The event is an attribute of an HTML element                     <ul style="list-style-type: none"> <li>■ eventName starts with on</li> </ul> </li> <li>■ Example:                     <pre>&lt;body onLoad = "myHandler()"&gt; &lt;body onLoad = "instruction1;...; instructionN;"&gt;</pre> </li> </ul> </li> </ul> <p>Note: it is not possible to associate any event with any element since some events have no meaning or cannot arise for some element.</p>
<p>257</p>	<p>258</p>	<p>258</p>	<p>258</p>

## Event Object To Associate Events with Code

- Second Approach – to set the value of the property corresponding to the event to a specific function

```
<div style="position:absolute; left:300px; top:200px;"  
      id="but"> <button>Click</button>  
</div>  
<script type="text/javascript" src=".//myscript11.js"> </script>  
  
// myscript11.js  
but.onmouseover=moveMouse; //Event handlers are function references  
function moveMouse()  
{  
    but.style.top= (parseInt(but.style.top)+ diff[(i+3)%4]) + "px";  
    but.style.left=(parseInt(but.style.left)+ diff[(i++)%4])+ "px";  
}
```

**Note: no parentheses**

259

## Event Object To Associate Events with Code

- Third Approach – Specifying an event handler with a Function object.

```
// La funzione aggiungi_gestori installa un insieme di gestori di  
// eventi su ogni elemento di un form f, senza controllare se  
// l'elemento supporta tutti questi tipi di eventi  
  
function aggiungi_gestori(f) {  
    var gestore_click = new Function("dettaglia(this, 'Click')");  
    var gestore_change = new Function("dettaglia(this, 'Change')");  
    var gestore_focus = new Function("dettaglia(this, 'Focus')");  
    var gestore.blur = new Function("dettaglia(this, 'Blur')");  
    var gestore_select = new Function("dettaglia(this, 'Select')");  
    var gestore_dblclick = new Function("dettaglia(this, 'dblClick')");
```

261

## Event Object To Associate Events with Code

- Fourth approach – addEventListener(type, listener[, useCapture])
- The EventTarget.addEventListener() method registers the specified listener on the EventTarget it is called on. The event target may be an Element in a document, the Document itself, a Window, or any other object that supports events
  - Type - A string representing the event type to listen for
  - Listener - the object that receives a notification when an event of the specified type occurs
  - useCapture - If true, useCapture indicates that the user wishes to initiate capture. After initiating capture, all events of the specified type will be dispatched to the registered listener before being dispatched to any EventTarget beneath it in the DOM tree.

263

## Event Object To Associate Events with Code

- Third Approach – Specifying an event handler with a Function object. Function objects created with the Function constructor are evaluated each time they are used.

```
function dettaglia(elemento, evento) {  
    var t = elemento.form.area_testo;  
    var nome_elemento = elemento.name; var valore = " ";  
    if ((elemento.type == "select-one") || (elemento.type == "select-multiple")){ for (var i = 0; i < elemento.options.length; i++)  
        if (elemento.options[i].selected)  
            valore += elemento.options[i].value + " "; }  
    else if (elemento.type == "textarea") valore = "...";  
    else valore = elemento.value;  
    var mess = evento + ": " + nome_elemento + ' (' + valore + ')\n';  
    t.value += mess;
```

260

## Event Object To Associate Events with Code

- Third Approach – Specifying an event handler with a Function object.

```
for(var i = 0; i < f.elements.length; i++) {  
    var e = f.elements[i];  
    e.onclick = gestore_click;  
    e.onchange = gestore_change;  
    e.onfocus = gestore_focus;  
    e.onblur = gestore.blur;  
    e.onselect = gestore_select;  
    e.ondblclick = gestore_dblclick;
```

}

262

## Event Object To Associate Events with Code

- Fourth approach – addEventListener(type, listener[, useCapture])

```
// Function to change the content of t2  
function modifyText() {  
    var t2 = document.getElementById("t2");  
    if (t2.firstChild.nodeValue == "three") {  
        t2.firstChild.nodeValue = "two";  
    } else {  
        t2.firstChild.nodeValue = "three";  
    }  
}  
// add event listener to table  
var el = document.getElementById("outside");  
el.addEventListener("click", modifyText, false);
```

264

## Events

- Main events

Attribute	The event occurs when...	IE	F	O	W3C
onblur	An element loses focus	3	1	9	Yes
onchange	The content of a field changes	3	1	9	Yes
onclick	Mouse clicks an object	3	1	9	Yes
ondblclick	Mouse double-clicks an object	4	1	9	Yes
onerror	An error occurs when loading a document or an image	4	1	9	Yes
onfocus	An element gets focus	3	1	9	Yes
onkeydown	A keyboard key is pressed	3	1	No	Yes

265

## Events

- The events are applicable to specific elements
- For instance,
  - onBlur is applicable to only object window and all the elements of a form
  - onChange is applicable to only the fields <input>, <textarea> and <select> of a form
  - onMouseOut is applicable to elements links and areas
  - onResize is applicable to document, frame and window

267

## Event order

- Two models
  - Capturing – the event on element1 takes place first (Netscape)
  - Bubbling – the event on element2 takes precedence (Microsoft)

269

## Events

Attribute	The event occurs when...	IE	F	O	W3C
onkeypress	A keyboard key is pressed or held down	3	1	9	Yes
onkeyup	A keyboard key is released	3	1	9	Yes
onmousedown	A mouse button is pressed	4	1	9	Yes
onmousemove	The mouse is moved	3	1	9	Yes
onmouseout	The mouse is moved off an element	4	1	9	Yes
onmouseover	The mouse is moved over an element	3	1	9	Yes
onmouseup	A mouse button is released	4	1	9	Yes
onresize	A window or frame is resized	4	1	9	Yes
onselect	Text is selected	3	1	9	Yes
onunload	The user exits the page	3	1	9	Yes

266

## Events

```
<script type="text/javascript">
function setStyle(x)
{
  document.getElementById(x).style.background="yellow";
}
function resetStyle(x)
{
  document.getElementById(x).style.background="white";
}
</script>
</head>
<body>
<div>
First name: <input type="text" onfocus="setStyle(this.id)">
onblur="resetStyle(this.id)" id="fname"><br>
Last name: <input type="text" onfocus="setStyle(this.id)">
onblur="resetStyle(this.id)" id="lname"></div>
</body>
```

268

## Event order

### Event capturing

- The event handler of element1 fires first, the event handler of element2 fires last

270

## Event order

### Event bubbling

- The event handler of element2 fires first, the event handler of element1 fires last

271

## Event order

### W3C model

- W3C has decided to take a middle position in this struggle. Any event taking place in the W3C event model is first captured until it reaches the target element and then bubbles up again

272

## Event Handler

- The Web developer can choose whether to register an event handler in the capturing or in the bubbling phase.
  - This is done through the `addEventListener()`
  - If its last argument is true the event handler is set for the capturing phase
  - If it is false the event handler is set for the bubbling phase

273

## Event Handler

```
element1.addEventListener('click',doSomething2,true)
```

```
element2.addEventListener('click',doSomething,false)
```

If the user clicks on element2 the following happens:

- The click event starts in the capturing phase. The event looks if any ancestor element of element2 has a `onclick` event handler for the capturing phase.
- The event finds one on element1. `doSomething2()` is executed.
- The event travels down to the target itself, no more event handlers for the capturing phase are found. The event moves to its bubbling phase and executes `doSomething()`, which is registered to element2 for the bubbling phase.
- The event travels upwards again and checks if any ancestor element of the target has an event handler for the bubbling phase. This is not the case, so nothing happens.

## Event Handler

```
element1.addEventListener('click',doSomething2,false)
element2.addEventListener('click',doSomething,false)
```

Now if the user clicks on element2 the following happens:

- The click event starts in the capturing phase. The event looks if any ancestor element of element2 has a `onclick` event handler for the capturing phase and doesn't find any.
- The event travels down to the target itself. The event moves to its bubbling phase and executes `doSomething()`, which is registered to element2 for the bubbling phase.
- The event travels upwards again and checks if any ancestor element of the target has an event handler for the bubbling phase.
- The event finds one on element1. Now `doSomething2()` is

275

## Event Handler

- If you would like to stop the propagation
  - IE - `window.event.cancelBubble = true`
  - W3C model - `e.stopPropagation();`

```
function doSomething(e)
{
  if (!e) var e = window.event;
  e.cancelBubble = true;
  if (e.stopPropagation) e.stopPropagation();
}
```

276

## Event Handler

- Current Target
    - During the capturing and bubbling phases the target does not change: it always remains a reference to element 2
- ```
element1.onclick = doSomething;
element2.onclick = doSomething;
```
- How do you know which HTML element is currently handling the event?
  - Target/srcElement don't give a clue, they always refer to element2
  - In W3C has been added currentTarget (not in IE).
  - You can however use the this keyword.

277

## How to write a code independent of the browser for handling events

- To access the event object
  - function handler(e) {
 

```
e=(!e) ? window.event : e;
```

If the browser is IE, the parameter e is not initialized. Thus, e has to be explicitly initialized to contain the Event object
- To refer to the object where the event is arisen
  - obj=(e.target != null) ? e.target : e.srcElement

279

## Event Object Properties

| Property      | Description                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------|
| bubbles       | Returns a Boolean value that indicates whether or not an event is a bubbling event                   |
| cancelable    | Returns a Boolean value that indicates whether or not an event can have its default action prevented |
| currentTarget | Returns the element whose event listeners triggered the event                                        |
| eventPhase    | Returns which phase of the event flow is currently being evaluated                                   |
| target        | Returns the element that triggered the event                                                         |
| timeStamp     | Returns the time stamp, in milliseconds, from the epoch (system start or event trigger)              |
| type          | Returns the name of the event                                                                        |
| isTrusted     | Indicates whether or not the event was initiated by the browser or by a script                       |

281

## Event Object Properties

- When an event occurs, the browsers make an Event object available to the handlers
- The object provides information regarding the event
- Differences between browsers
  - Typically, the Event object is passed to the handler except for Internet Explorer
    - In IE, the Event object is made available as a property of the object Window, that is, a global variable
  - Some properties have different names
    - For instance, to find the reference to the element where the event is arisen:
      - target (in FireFox)
      - srcElement (in IE)

278

## Event Object Properties

| Property      | Description                                                                        | IE | F  | W3C |
|---------------|------------------------------------------------------------------------------------|----|----|-----|
| altKey        | Returns whether or not the "ALT" key was pressed when an event was triggered       | 6  | 19 | Yes |
| button        | Returns which mouse button was clicked when an event was triggered                 | 6  | 19 | Yes |
| clientX       | Returns the horizontal coordinate of the mouse pointer when an event was triggered | 6  | 19 | Yes |
| clientY       | Returns the vertical coordinate of the mouse pointer when an event was triggered   | 6  | 19 | Yes |
| ctrlKey       | Returns whether or not the "CTRL" key was pressed when an event was triggered      | 6  | 19 | Yes |
| metaKey       | Returns whether or not the "meta" key was pressed when an event was triggered      | 6  | 19 | Yes |
| relatedTarget | Returns the element related to the element that triggered the event                | No | 19 | Yes |
| screenX       | Returns the horizontal coordinate of the mouse pointer when an event was triggered | 6  | 19 | Yes |
| screenY       | Returns the vertical coordinate of the mouse pointer when an event was triggered   | 6  | 19 | Yes |
| shiftKey      | Returns whether or not the "SHIFT" key was pressed when an event was triggered     | 6  | 19 | Yes |

280

## Event Object Events

Event Handlers can be used in three different ways to trigger a function

### 1. Link Events

Places an Event Handler as an attribute within an `<a href = >` tag

For example:

```
<div>
<a href="#" onClick="alert('Ooo, do it again!');">
  Click on me!</a>
<a href="javascript:void()" onClick="alert('Ooo, do
    it again!');"> Click on me! </a>
<a href="javascript:alert('Ooo, do it again!')">
  Click on me!</a>
</div>
```

282

## Event Object (Events)

Note: No <script> tag.

- Anything that appears in the quotes of an onClick or an onMouseOver is automatically interpreted as JavaScript.
- href="#" tells the browser to look for the anchor #, but there is no anchor "#", so the browser goes to the top of the page since it could not find the anchor.
- <a href="javascript:void(' ')> tells the browser not to go anywhere –
  - it "deadens" the link when you click on it.
  - href="javascript: is the way to call a function when a link (hyperlink or an HREFed image) is clicked.

283

## Event Object (Events)

```
function setStyle(fld)
{fld.style.backgroundColor="yellow"}
</script>
</head>

<body>
<form id="frm1" action="form_action.asp">
<p>Insert a Number: <input type="input" required
   pattern="^[0-9]+$" id="idname"
   onfocus="setStyle(this)"
   onchange="checkField(this)"></p>
</form>
</body>
</html>
```

285

## Event Object (Example)

```
<head>
<script type="text/javascript">
var loaded = "false";
function doit() {
    alert('Everything is "loaded" and loaded = ' + loaded);
}
function bye(){alert("Bye bye");}
</script>
</head>
```

287

## Event Object (Events)

### 2. Actions within forms

```
function checkField(fld){
    if (fld.checkValidity() && fld.value>100)
    {
        alert("Correct number");
        fld.style.backgroundColor="white";
    }
    else
    { alert("Please enter a number greater than 100");
        fld.value=null;
        fld.style.backgroundColor="red";
        setTimeout(function()
        {document.getElementById('idname').focus();},1000);
    }
}
```

284

## Event Object (Events)

### 3. Body onLoad and unLoad

- These Event Handlers are defined in the <body> or <frameset> tag of an HTML file and are invoked when the document or frameset are fully loaded or unloaded.
- If you set a flag within the onLoad Event Handler, other Event Handlers can test this flag to see if they can safely run, with the knowledge that the document is fully loaded and all objects are defined.
- Used to check the visitor's browser type and version, and load the proper version of the web page
- Used to deal with cookies that should be set when a user enters or leaves a page
- onload - allows launching a particular JavaScript function upon the completion of initially loading the document
- onunload - is triggered when the user "unloads" or exits the document

286

## Event Object (Example)

```
<body onload="loaded='true'; onunload="bye()">
<form id="frm1" action="form_action.asp">
<p>
<input type="button" value="Press me"
   onClick="if (window.loaded) doit();">
</p>
</form>
</body>
```

288

## Examples (keydown event)

### Move a figure on the page

```
<html>
<head>
<title> Events </title>
<meta http-equiv="Content-Type"
      content="text/html; charset=us-ascii">
</head>
<body onload="set()">
<div id="mydiv"
     style="position:absolute; left:450px; top:300px;">
  
</div>
<script type="text/javascript"
       src=".//myscript12.js">
</script>
</body>
</html>
```

289

## Timer Events

**setInterval("function()", delay)**

Calls a function repeatedly, with a fixed time delay between each call to that function. The setInterval() method will continue calling the function until clearInterval() is called, or the window is closed. delay is expressed in millisec.

**setTimeout("function()", delay)**

Calls a function after a specified number "delay" of milliseconds.

**clearInterval(id\_of\_setinterval)**

Clears a timer set with the setInterval() method. The ID value returned by setInterval() is used as the parameter for the clearInterval() method.

**clearTimeout(id\_of\_settimeout)**

Clears a timer set with the setTimeout() method. The ID value returned by setTimeout() is used as the parameter for the clearTimeout() method.

291

## Timer Events

```
function stopTextColor()
{
  clearInterval(intervalID);
}
</script>
</head>

<body onload="changeColor();">
<div id="my_box">
  <p>Hello World</p>
  <button onclick="stopTextColor();">Stop</button>
</div>
</body>
</html>
```

293

## Examples (keydown event)

### Move a figure on the page

```
var elem = document.getElementById('mydiv');
function set() {document.onkeydown = onKeyHandler;}
function onKeyHandler(e) {
  e = (!e) ? window.event : e;
  var key = (e.which != null) ? e.which : e.keyCode; //Explorer -> !e //Firefox -> e.which
  switch(key){
    case 37: move(-3, 0); break; // left
    case 38: move(0, -3); break; // up
    case 39: move(3, 0); break; // right
    case 40: move(0, 3); break; // down
    default: window.alert('stop'); }
}
function move(dx,dy) {
  elem.style.left = parseInt(elem.style.left) + dx + "px";
  elem.style.top = parseInt(elem.style.top) + dy + "px"; }
```

290

## Timer Events

<!-- Head -->

```
<title>setInterval/clearInterval example</title>
<script type="text/javascript">
var intervalID;
function changeColor()
{
  intervalID = setInterval(flashText, 1000);
}

function flashText()
{
  var elem = document.getElementById("my_box");
  if (elem.style.color == 'red')
    elem.style.color = 'blue';
  else
    elem.style.color = 'red';
}
```

292

## Timer Events

## Examples

294

## Dynamic Effects

- Dynamic effects are obtained by combining events and properties of the different objects
- Examples
  - Rollover – change of the images when the user passes over the images with the cursor of the mouse
  - Brief Animations
  - Sliding text
  - Gradual change of the background colour
  - Layer management

295

## Rollover

```
<body>
<div>

</div>
<script type="text/javascript" src="./myscript13.js"></script>
</body>
```

296

## Rollover

```
//myscript13.js
var img1 = new Array(2); //
img1[0] = new Image(); img1[1] = new Image();
var img2 = new Array(2); img2[0]= new Image();
img2[1]= new Image();
img1[0].src="a.jpg"; img1[1].src="b.gif"; //default images
img2[0].src="b.gif"; img2[1].src="a.jpg";//rollover images

function modify(i,type) {
  if (type == "over")
    document.images[i].src = img2[i].src; //mouseover
  else   document.images[i].src = img1[i].src;//mouseout
}
```

297

## Sliding Text

```
//myscript14.js
var text = "Example of Sliding Text .....";
function slide() {
var firstchar = text.charAt(0);
text = text.slice(1,text.length) + firstchar;
document.forms[0].mytext.value = text}
```

299

## Sliding Text

```
<style type="text/css">
#slidText { color : red; background:black}
</style>
</head>
<body onload="setInterval('slide()',100);">
<form action='#!'>
<p> <input type="text"
size="30"
name="mytext"
id = "slidText"
style="border: solid;"> </p> </form>
<script type="text/javascript" src="./myscript12.js"></script>
</body>
```

298

## Managing Layers

- Layers allow designers to (partially) superimpose an content on another content
- The element HTML div permits managing the layers using the following properties;
  - **position:** identifies the position of the element in the page
    - Values: absolute, fixed and relative
  - **left, right, top, bottom:** identify the position of the left-top or the right-bottom margin with respect to the reference container.
  - **height and width:** specify the width and height of the layer in pixels
  - **z-index:** specifies the layer (positive integer) on the z-axis
  - **visibility:** determines whether the element is visible or not.
    - Values: hidden and visible

300

## Managing Layers Example

```
<link rel="stylesheet" href="mystyleJS.css" type="text/css"
      media="screen">
</head>
<body>
  <h1> Properties of the levels </h1>
  <div id="div1" style= "position: absolute; left: 300px; top:150px;
    width:300px; height:150px; z-index: 1"> Red </div>
  <div id="div2" style= "position: absolute; left: 350px; top:200px;
    width:300px; height:150px; z-index: 2"> Blu </div>
  <div id="div3" style= "position: absolute; left: 400px; top:250px;
    width:300px; height:150px; z-index: 3"> Green </div>
```

301

## Managing Layers Example (myscript15.js)

```
var ERROR = false;
function read(i) { value = 0;
  with (document.mymodule) {
    switch (i) { case 1: return idiv.value; break;
      case 2: value = top.value; break;
      case 3: value = left.value; break;
      case 4: value = width.value; break;
      case 5: value = height.value; break;
      case 6: value = level.value; }
  }
  value = parseInt(value);
  if ((value < 0) || isNaN(value))
  { window.alert("Error in the field n." + i);
    ERROR = true; } return value; }
```

303

## Managing Layers Example (mystyleJS.js)

```
div { border: outset;
  font-size: xx-large;
  font-weight: bolder;
  overflow: hidden;}
#div1 { background-color: red; }
#div2 { background-color: blue; }
#div3 { background-color: green; }
#control { background-color: azure; z-index: 0;
  width: 15em; padding: 5px;
  font-size: medium; font-weight: normal;
}
```

305

## Managing Layers Example

```
<div id="control">
<form action="#" name="mymodule" id="mymodule">
<p>
  1) Insert the block:<br>
  <select name="idiv">
    <option value="div1" selected> red </option>
    <option value="div2"> blu </option>
    <option value="div3"> green </option>
  </select><br>
  2) Insert the distance from the top:<br>
  <input type="text" size="5" name="top" value="150"><br>
  //...
  <input type="button" value="set" onclick="set()">
  //...
<script type="text/javascript" src="./myscript16.js">
```

302

## Managing Layers Example (myscript15.js)

```
function set() { var i = read(1);
  var x = read(2);
  var y = read(3);
  var w = read(4);
  var h = read(5);
  var z = read(6);
  if (!ERROR) { var mydiv = document.getElementById(i);
    mydiv.style.top = x + "px";
    mydiv.style.left = y + "px";
    mydiv.style.width = w + "px";
    mydiv.style.height = h + "px";
    mydiv.style.zIndex = z + "";
    } }
  ERROR = false; }
```

304

## Validation of data inserted into a Form

- JavaScript allows verifying the data inserted into a form directly on the client-side
- Using handlers of appropriate events (onClick and onBlur), the data can be analysed and messages can be sent to the user
  - onClick – when the form is completed and sent to the server
  - onBlur – when the focus is passed on another element
- Typically, the verification is performed only on the input text fields

306

## Validation of data inserted into a Form

### Two examples

- Validation of data
- Assessment of the answers to a quiz

### Validation

Name (\*)  
  
 Surname (\*)  
  
 Age:  
  
 City:  
  
 Zip Code (\*)

### Quiz

- 1) What is the keyword in Javascript for defining a function?  
 var  
 function  
 script
- 2) What is not a valid comment in Javascript?  
 /\*...\*/  
 /\*\_/\*  
 /\*.../  
 /\*...//
- 

307

## Validation of data inserted into a Form

```
var existALPHANUMERICAL = /w/;
var existNONALPHANUMERICAL = /W/;
var existNONNUMERICAL = /D/;
var existNUMERICAL = /d/;
var exist5NUMERICAL = /^d{5}$/;
function error(idmess, field)
{ window.alert(MESSAGES[idmess] + field.name);
  field.focus(); field.select();
}
```

309

## Validation of data inserted into a Form

```
function validate()
{
if (isTrue(existALPHANUMERICAL, shouldBeALPHANUMERICAL, false, 0))
  return;
if (isTrue(existNONALPHANUMERICAL, shouldBeALPHANUMERICAL, true, 0))
  return;
if (isTrue(existNONNUMERICAL, shouldBeNUMERICAL, true, 1))
  return;
if (isTrue(exist5NUMERICAL, shouldBe5NUMBERS, false, 2)) return;
if (isTrue(existNUMERICAL, shouldBeALPHABETICAL, true, 3)) return;
if (isTrue(existNONALPHANUMERICAL, shouldBeALPHABETICAL, true, 3))
  return;
  window.alert(MESSAGES[MESSAGES.length-1]);
}
```

311

## Validation of data inserted into a Form

### Validation of the data inserted by using the previous form

```
var fields = document.getElementsByTagName("input");
var shouldBeALPHANUMERICAL = [0, 1, 4]; // (1)
var shouldBeNUMERICAL = [2, 4];
var shouldBeALPHABETICAL = [0, 1, 3];
var shouldBe5NUMBERS = [4];
var MESSAGES = [ "The following field does not have valid symbols: ",
  "The following field is not exclusively numerical: ",
  "The following field must have five digits: ",
  "The following field must have only letters: ",
  "...",
  "OK"];
```

308

## Validation of data inserted into a Form

```
function isTrue(COND, ELEM, BOOL, MESS) {
  for (var i=0; i<ELEM.length; i++) {
    var j = ELEM[i];
    field = fields[j];
    if (COND.test(field.value) == BOOL) {
      error(MESS, field);
      return true;
    }
  }
  return false;
}
```

310

## Assessment of the answers to a quiz

```
<form action="#" name="mymodule" id="mymodule">
<script type="text/javascript">
<!--
for (var i=0; i<Queries.length; i++)
{
  document.writeln("<div>" + (i+1) + ")" + Queries[i] + "<br>");
  for (var j=0; j<Options[i].length; j++)
    document.writeln("<input type='radio' name='q" + i + "'>" +
      Options[i][j] + "<br>");
  document.writeln("<hr></div>");
}
-->
</script>
<p>
<input type="button" value="VERIFY" onclick="check()"></p>
```

312

## Assessment of the answers to a quiz

//myscript18.js

```
var Queries = [
    "What is the keyword in Javascript for defining a function?",
    "What is not a valid comment in Javascript?",
    "What is the handler for the 'loss of active state' event?",
    "Which operator can be used to instance an object?",
    "To periodically call a function you use the method:"];
var Options = [ ["var", "function", "script"],
    ["\\*...*\\/*.../*", "//...", "//..."],
    ["onFocus", "onBlur", "onClick"],
    ["create", "new", "add"],
    ["window.setInterval", "window.setTimeout", "date.setTime"]];
```

313

## Web Storage

315

## Cookie

- Cookies may be set by the server with or without an expiration date.
  - Cookies without an expiration date exist until the browser terminates
  - Cookies with an expiration date may be stored by the browser until the expiration date passes.
  - Users may also manually delete cookies in order to save space or to avoid privacy issues.
- Cookies may be used to remember the information about the user who has visited a website in order to show relevant content in the future.
  - For example a web server may send a cookie containing the username last used to log in to a web site so that it may be filled in for future visits.

317

## Assessment of the answers to a quiz

//myscript18.js

```
var Answers = [ 0,1,0, 0,1,0,0, 0,1,0, 0,1,0, 1,0,0];
function check() { var score = 0;
    var answers =
        document.getElementsByTagName("INPUT");
    for (var i = 0; i < answers.length-1; i++)
        if (answers[i].checked)
            if (Answers[i]===1) score++;
            else score--;
    window.alert("Your score is: " + score);
    document.myModule.reset();
}
```

314

## Cookie

- A cookie is a piece of text stored by a user's web browser.
- A cookie can be used for
  - authentication,
  - storing site preferences,
  - shopping cart contents,
  - the identifier for a server-based session.
- A cookie consists of one or more name-value pairs containing bits of information, which may be encrypted for information privacy and data security purposes.
- The cookie is sent as an HTTP header by a web server to a web browser and then sent back unchanged by the browser each time it accesses that server.

316

## Cookie

```
function setCookie(name, value, expires, path, domain,
    secure )
{ // set time, it's in milliseconds
var today = new Date();
if ( expires ) { expires = expires * 1000 * 60 * 60 * 24; }
var expires_date = new Date( today.getTime() + expires );
document.cookie = name + "=" + escape( value ) +
( ( expires ) ? ";expires=" + expires_date.toGMTString() : "" ) +
( ( path ) ? ";path=" + path : "" ) +
( ( domain ) ? ";domain=" + domain : "" ) +
( ( secure ) ? ";secure" : "" );
}
```

318

## Cookie

### Parameters:

- **name** – name of the cookie
- **value** – value of the cookie
- **expire** – the time the cookie expires
- **path** – path on the server in which the cookie will be available on. If set to '/', the cookie will be available within the entire domain.
- **domain** - The domain that the cookie is available to. To make the cookie available on all subdomains of example.com (including example.com itself) then you'd set it to '.example.com'.
- **secure** - Indicates that the cookie should only be transmitted over a secure HTTPS connection from the client. When set to **TRUE**, the cookie will only be set if a secure connection exists.

319

## Cookie

```
// if the extracted name matches passed check_name
if ( cookie_name == check_name )
{
    b_cookie_found = true;
    // we need to handle case where cookie has no value
    // but exists (no = sign, that is):
    if ( a_temp_cookie.length > 1 )
        { cookie_value =
unescape(a_temp_cookie[1].replace(/\s+|\s+$/.g, " "));
    }
// note: if cookie is initialized but no value, null is returned
    return cookie_value;
}
a_temp_cookie = null; cookie_name = "";
}
```

321

## Cookie

```
function checkCookie()
{ username=getCookie('username');
  if (username!=null && username!="")
  { alert('Welcome again '+username+'!'); }
else
  { username=prompt('Please enter your name:','');
  if (username!=null && username!="")
    { setCookie('username',username,100,'/');
    }
  }
...
<body onLoad="checkCookie()">
<p><a href="javascript:deleteC()">
Click to delete the cookie</a></p>
</body>
```

323

## Cookie

```
function getCookie( check_name ) {
// first we'll split this cookie up into name/value pairs
// note: document.cookie only returns name=value, not the other
components
var a_all_cookies = document.cookie.split( ';' );
var a_temp_cookie = "";
var cookie_name = "";
var cookie_value = "";
var b_cookie_found = false; // set boolean t/f default f
for ( i = 0; i < a_all_cookies.length; i++ )
{
    // now we'll split apart each name=value pair
    a_temp_cookie = a_all_cookies[i].split( '=' );
    // and trim left/right whitespace while we're at it
    cookie_name = a_temp_cookie[0].replace(/\s+|\s+$/.g, "");
```

320

## Cookie

```
if ( !b_cookie_found )
{ return null;
}

function deleteCookie( name, path, domain ) {
name=prompt('Please enter the cookie to remove:','');
if ( getCookie( name ) ) document.cookie = name + "=" +
( ( path ) ? ";path=" + path : "" ) +
( ( domain ) ? ";domain=" + domain : "" ) +
";expires=Thu, 01-Jan-1970 00:00:01 GMT";
}

function deleteC()
{ name=prompt('Please enter the cookie to remove:','');
deleteCookie(name,'/');
}
```

322

## Session and Local Storage

- Cookies are extremely limited in size. Generally, only about 4KB.
- Cookies are transmitted back and forth from server to browser on every request scoped to that cookie.
  - security risks
  - network bandwidth consumption
- The same results could be achieved without involving a network or remote server and storing up to a few megabytes.
  - **sessionStorage** – values survive either across page loads in a single window or tab
  - **localStorage** – values survive across browser restarts

324

## Session and Local Storage Browser Support

```
function checkStorageSupport() {
//sessionStorage
if (window.sessionStorage) {
alert('This browser supports sessionStorage');
} else {
alert('This browser does NOT support sessionStorage');
}
//localStorage
if (window.localStorage) {
alert('This browser supports localStorage');
} else {
alert('This browser does NOT support localStorage');
}
}
```

325

## Session and Local Storage How long do the values persist?

- Objects in sessionStorage
  - These objects will persist as long as the browser window (or tab) is not closed.
  - Session storage is perfect for short-lived processes that would normally be represented in wizards or dialogs.
  - Solves a problem that has plagued many web-applications: scoping of values.

327

## Local Versus Session Storage

- localStorage – values survive across browser restarts

sessionStorage	localStorage
Values persist only as long as the window or tab in which they were stored.	Values persist beyond window and browser lifetimes.
Values are only visible within the window or tab that created them.	Values are shared across every window or tab running at the same origin.

- The storage interface

```
interface Storage {
  readonly attribute unsigned long length;
  getter DOMString key(in unsigned long index);
  getter any getItem(in DOMString key);
  setter creator void setItem(in DOMString key, in any data);
  deleter void removeItem(in DOMString key);
  void clear();
};
```

329

## Session and Local Storage Browser Support

- Setting a value

```
window.sessionStorage.setItem('myFirstKey', 'myFirstValue');
```
- Retrieve a value

```
window.sessionStorage.getItem('myFirstKey')
```
- setItem and getItem calls can be avoided entirely by simply setting and retrieving values corresponding to the key-value pair directly on the sessionStorage object.

```
window.sessionStorage.myFirstKey = 'myFirstValue';
window.sessionStorage.myFirstKey;
```

326

## Session and Local Storage How long do the values persist?

- The figure shows the problem of value scoping with cookies
  - Solution: sessionStorage allows temporary values like a departure date to be saved across pages that access the application but not leak into other windows where the user is also browsing for flights. Therefore, those preferences will be isolated to each window where the corresponding flights are booked.

328

## Storage

- length – specifies how many key-value pairs are currently stored in the storage object.
- key(index) – allows retrieval of a given key.
- getItem(key) – is one way to retrieve the value based on a given key.
- setItem(key, value) – will put a value into storage under the specified key name, or replace an existing value if one already exists under that key name.
- removeItem(key) – If a value is currently in storage under the specified key, this call will remove it. If no item was stored under that key, no action is taken.
- clear() – removes all values from the storage list.

330

## Communicating Web Storage Updates

- To register to receive the storage events of a window's origin, simply register an event listener, for example:

```
window.addEventListener("storage", displayStorageEvent, true);
```

- The StorageEvent Interface

```
interface StorageEvent : Event {
  readonly attribute DOMString key;
  readonly attribute any oldValue;
  readonly attribute any newValue;
  readonly attribute DOMString url;
  readonly attribute Storage storageArea;
};
```

331

## Display Content of a Storage Event

```
// display the contents of a storage event
function displayStorageEvent(e) {
  var logged = "key:" + e.key + ", newValue:" + e.newValue + ", "
  + "oldValue:" +
  e.oldValue + ", url:" + e.url + ", storageArea:" + e.storageArea;
  alert(logged);
}

// add a storage event listener for this origin
window.addEventListener("storage", displayStorageEvent, true);
```

333

## Storage Event

- key** – contains the key value that was updated or removed in the storage.
- oldValue** – contains the previous value corresponding to the key before it was updated, and the **newValue** contains the value after the change.
- url** – points to the origin where the storage event occurred.
- storageArea** – provides a convenient reference to the **sessionStorage** or **localStorage** where the value was changed. This gives the handler an easy way to query the storage for current values or make changes based on other storage changes.

332

## Example

```
<body>
  Key: <input type="text" id="key"><br>
  Value: <input type="text" id="value"><br>
  <input type="button" id="add" value="Add to Storage">&nbsp;
  <input type="button" id="remove" value="Remove from
  Storage">&nbsp;
  <input type="button" id="clear" value="Clear Storage"><br>
  Contents of Local Storage:<br>
  <div id="content"></div>
</body>
```

Note that the example does not work correctly in Chrome if the page runs from the file protocol (<file:///>).

334

 <h2>Progettazione Web</h2> <h3>PHP</h3> <p><b>Francesco Marcelloni</b></p> <p>Dipartimento di Ingegneria dell'Informazione Università di Pisa ITALY</p>	 <p>1</p>	<h2>What is PHP</h2> <ul style="list-style-type: none"> <li>■ PHP is recursive acronym for PHP: Hypertext Preprocessor</li> <li>■ PHP is a server-side scripting language</li> <li>■ PHP scripts are executed on the server</li> <li>■ PHP supports many databases (MySQL, Informix, Oracle, Sybase, Solid, PostgreSQL, Generic ODBC, etc.)</li> <li>■ PHP is an open source software</li> <li>■ PHP is free to download and use</li> </ul>	 <p>2</p>
 <p>3</p>	<h2>What is a PHP file</h2> <ul style="list-style-type: none"> <li>■ PHP files can contain text, HTML tags and scripts</li> <li>■ PHP files are returned to the browser as plain HTML</li> <li>■ PHP files have a file extension of ".php", ".php3", or ".phtml"</li> <li>■ PHP+MySQL <ul style="list-style-type: none"> <li>■ PHP combined with MySQL are cross-platform (you can develop in Windows and serve on a Unix platform)</li> </ul> </li> </ul>	 <p>4</p>	<h2>Why PHP?</h2> <ul style="list-style-type: none"> <li>■ PHP runs on different platforms (Windows, Linux, Unix, etc.)</li> <li>■ PHP is compatible with almost all web servers used today (Apache, IIS, etc.)</li> <li>■ PHP is FREE to download from the official PHP resource: <a href="http://www.php.net">www.php.net</a></li> <li>■ PHP is easy to learn and runs efficiently on the server side</li> </ul>
 <p>5</p>	<h2>Where to Start?</h2> <ul style="list-style-type: none"> <li>■ To get access to a web server with PHP support, you can: <ul style="list-style-type: none"> <li>■ Install Apache (or IIS) on your own server, install PHP, and MySQL</li> <li>■ Or find a web hosting plan with PHP and MySQL support</li> </ul> </li> </ul>	 <p>6</p>	<h2>How is PHP included in HTML pages?</h2> <ol style="list-style-type: none"> <li>1. <code>&lt;?php echo 'if you want to serve XHTML or XML documents, do it like this'; ?&gt;</code></li> <li>2. <code>&lt;script language="php"&gt; echo 'some editors (like FrontPage) don\'t like processing instructions'; &lt;/script&gt;</code></li> <li>3. <code>&lt;? echo 'this is the simplest, an SGML processing instruction'; ?&gt; &lt;?= expression ?&gt; This is a shortcut for "&lt;? echo expression ?&gt;"</code></li> </ol> <p>Tags in 1. and 2. are both always available. Tag 1. is the most commonly used, and recommended, of the two.</p> <p>Short tags (example 3.) are only available when they are enabled via the <code>short_open_tag</code> <code>php.ini</code> configuration file directive, or if PHP was configured with the <code>--enable-short-tags</code> option.</p>

## PHP Syntax

- A PHP scripting block can be placed anywhere in the document.
- A PHP file normally contains HTML tags, just like an HTML file, and some PHP scripting code

```
<?php if ($expression) { ?>
    <strong>This is true.</strong>
<?php } else { ?>
    <strong>This is false.</strong>
<?php } ?>
```

- When PHP hits the **?>** closing tags, it simply starts outputting whatever it finds (except for an immediately following newline) until it hits another opening tag.

7

## Instruction Separation and Comments

- NOTE:** Each code line in PHP must end with a **semicolon**. The closing tag of a block of PHP code automatically implies a semicolon; you do not need to have a semicolon terminating the last line of a PHP block.
- NOTE:** The **closing tag** for the block will include the immediately trailing newline if one is present.
- NOTE:** In PHP, **comments** are expressed as:
  - // to make a single-line comment
  - /\* to make a large comment block \*/
  - # to make a single comment as in Unix shell

9

## PHP Types

PHP supports **eight primitive types**.

- Four scalar types:
  - boolean
  - integer
  - float (floating-point number)
  - string
- Two special types:
  - NULL
  - resource
- Two compound types:
  - array
  - object

11

## PHP Example

```
<!DOCTYPE html>
<html lang="en">
<head>
<meta charset="utf-8">
<title> PHP Example </title>
</head>
<body>
    <p><?php echo "Hi, I'm a PHP script!"; ?></p>
</body>
</html>
```

- NOTE:** The **file must have a .php extension**. If the file has a .html extension, the PHP code will not be executed.

8

## PHP Variables

- All variables in PHP start with a \$ sign symbol.  
`$var_name = value;`
- In PHP, a variable does not need to be declared before adding a value to it.
- PHP automatically converts the variable to the correct data type, depending on its value.
- A variable name is case-sensitive and must start with a letter or an underscore "\_".
- A variable name can only contain alpha-numeric characters and underscores (a-z, A-Z, 0-9, and \_).

10

## PHP Types Boolean and Integer

- Boolean**
  - To specify a boolean literal, use the keywords TRUE or FALSE. Both are case-insensitive.
- Integer**
  - Integers can be specified in decimal (base 10), hexadecimal (base 16), or octal (base 8) notation, optionally preceded by a sign (- or +).
  - To use octal notation, precede the number with a 0 (zero).
  - To use hexadecimal notation precede the number with 0x.
  - Integer size** can be determined using the constant **PHP\_INT\_SIZE**, and maximum value using the constant **PHP\_INT\_MAX**.
  - If PHP encounters a number beyond the bounds of the integer type, it will be interpreted as a float instead. Also, an operation which results in a number beyond the bounds of the integer type will return a float instead.

12

## PHP Types Floating-Point Numbers

### Floating point numbers

```
<?php
$a = 1.234;
$b = 1.2e3;
$c = 7E-10;
?>

■ The size of a float is platform-dependent, although a maximum of ~1.8e308 with a precision of roughly 14 decimal digits is a common value (the 64 bit IEEE format).
```

13

## PHP Types String

### String

1. Single quoted
  - echo 'This is great <br>';
  - To specify a literal single quote, escape it with a backslash (\). To specify a literal backslash before a single quote, or at the end of the string, double it (\\).
2. Double quoted
  - The most important feature of double-quoted strings is the fact that variable names will be expanded.
  - Simple syntax
 

If a dollar sign (\$) is encountered, the parser will greedily take as many tokens as possible to form a valid variable name. Enclose the variable name in curly brackets to explicitly specify the end of the name.

15

## PHP Types String

### Complex Curly Syntax (example)

```
<?php
$great = 'fantastic';
// Won't work, outputs: This is { fantastic}
echo "This is {$great}";
// Works, outputs: This is fantastic
echo "This is ${great}";
// Works
echo "This square is {$square->width}00 centimeters
      broad.";
// Works
echo "This works: ${arr[4][3]}";
?>
```

17

### NULL

The special NULL value represents a variable with no value. NULL is the only possible value of type NULL.

A variable is considered to be null if:

- the constant NULL has been assigned to it
- it has not been set to any value yet.
- it has been unset().

The function is\_null() allows evaluating whether the value of a variable is NULL

### Resource

- A resource is a special variable, holding a reference to an external resource. Resources are created and used by special functions. For instance, dbase\_open() opens a database.

14

## PHP Types String

### Complex Curly Syntax

Any scalar variable, array variable or object property with a string representation can be included via this syntax.

- Simply write the expression the same way as it would appear outside the string, and then wrap it in { and }.
- Since { can not be escaped, this syntax will only be recognized when the \$ immediately follows the {.
- Use \\${\$ to get a literal \${}.
- PHP uses the same escape sequences ("\\") as in C++
   
\n, \t, \\, \\$, \", \0, [\0-\7]{1,3}, \x[\0-9A-Fa-f]{1,2}

16

## PHP Types String

### 3. Heredoc

A third way to delimit strings is the heredoc syntax: <<<. After this operator, an identifier is provided, then a newline. The string itself follows, and then the same identifier again to close the quotation. Heredoc text behaves just like a double-quoted string.

```
<?php
$str = <<<EOD
Example of string
spanning multiple lines
using heredoc syntax.
EOD;
echo $str;
?>
```

Output: Example of string spanning multiple lines using heredoc syntax.

18

## PHP Types String

- Characters within strings may be accessed and modified using **square array brackets** (or also braces)
 

```
<?php
// Get the first character of a string
$str = 'This is a test.';
$first = $str[0];

// Get the last character of a string.
$str = 'This is still a test.';
$last = $str[strlen($str)-1];

// Modify the last character of a string
$str = 'Look at the sea';
$str[strlen($str)-1] = 'e';
?>
```

19

## PHP Types String

- The **strpos()** function is used to search for character within a string. If no match is found, it will return FALSE
 

```
<?php
echo strpos("Hello world!","world");
?>
```
- The position of the string "world" in our string is position 6 (the first position in the string is 0).

21

## PHP Types String Functions

- string implode ( string \$glue , array \$pieces )** - Join array elements with a glue string.
 

```
<?php
$array = array('lastname', 'email', 'phone');
$comma_separated = implode(", ", $array);
echo "$comma_separated <br>"; // lastname,email,phone
$array = explode(", ", $comma_separated);
for($i = 0, $size = sizeof($array); $i < $size; ++$i)
    echo "$array[$i] "; // lastname email phone
?>
```

23

## PHP Types String

- Concatenation operator ('.')** - returns the concatenation of its right and left arguments.
- Concatenating assignment operator ('.=')** - appends the argument on the right side to the argument on the left side.

```
<?php
$a = "Hello ";
$b = $a . "World!"; // now $b contains "Hello World!"
$a = "Hello ";
$a .= "World!"; // now $a contains "Hello World!"
?>
```

20

## PHP Types String Functions

- string chr ( int \$ascii )** - Returns an one-character string containing the character specified by ascii.
- int ord ( string \$string )** - Returns the ASCII value of the first character of string.
- void echo ( string \$arg1 [, string \$... ] )** – Outputs all parameters. If you want to pass more than one parameter to echo(), the parameters must not be enclosed within parentheses. Es: echo \$first, "<br>";
- array explode ( string \$delimiter , string \$string [, int \$limit ] )** - Returns an array of strings (at most limit), each of which is a substring of string formed by splitting it on boundaries formed by the string delimiter.

22

## PHP Types String

- string number\_format ( float \$number , int \$decimals = 0 , string \$dec\_point = '.' , string \$thousands\_sep = ',' )** - generates the representation in string of a real number
  - Only one parameter:** number will be formatted without decimals, but with a comma (",") between every group of thousands.
  - Two parameters:** number will be formatted with decimals with a dot (".") in front, and a comma (",") between every group of thousands.
  - Four parameters:** number will be formatted with decimals, dec\_point instead of a dot (".") before the decimals and thousands\_sep instead of a comma (",") between every group of thousands.

24

## PHP Types String

```
<?php
$number = 1234.56;
// english notation (default)
$english_format_number = number_format($number);
// 1,235
// French notation
$nombre_format_francais = number_format($number, 2, ',', ',');
// 1 234,56
$number = 1234.5678;
// english notation without thousands separator
$english_format_number = number_format($number, 2, '.', '');
// 1234.57
?>
```

25

## PHP Types String

- **int strcmp ( string \$str1 , string \$str2 , int \$len )**

This function is similar to `strcmp()`, with the difference that you can specify the (upper limit of the) number of characters from each string to be used in the comparison.

Returns

- < 0 if str1 is less than str2;
- > 0 if str1 is greater than str2,
- 0 if they are equal.

27

## PHP Types Array

```
array( key => value
      , ...
    )
```

- **key may only be an integer or string**

(booleans are converted into integers and NULL is managed as an empty string)

- **value** may be any value of any type

```
<?php
$arr = array("foo" => "bar", 12 => true);
echo $arr["foo"]; // bar
echo $arr[12]; // 1
?>
```

29

- **void parse\_str ( string \$str [, array &\$arr ] )**

Parses str as if it were the query string passed via a URL and sets variables in the current scope.

```
<?php
$str = "first=value&arr[]=foo+bar&arr[]=baz";
parse_str($str);
echo "$first "; // value
echo "$arr[0] "; // foo bar
echo "$arr[1]<br>"; // baz
parse_str($str, $output);
echo "{$output['first']} "; // value
echo "{$output['arr'][0]} "; // foo bar
echo "{$output['arr'][1]}<br>"; // baz
```

?>

26

## PHP Types Array

- An array in PHP is actually **an ordered map**.

- A map is a type that associates values to keys.

- Optimized for several different uses:

- array, list (vector), hash table (an implementation of a map), dictionary, collection, stack, queue.

- Since array values can be other arrays, trees and multidimensional arrays are also possible.

- An array can be created by the **`array()`** language construct. It takes as parameters any number of comma-separated **key => value** pairs.

28

## PHP Types Array

- If a key is not specified for a value, the maximum of the integer indices is taken and the new key will be that value plus 1.

- If a key that already has an assigned value is specified, that value will be overwritten.

```
<?php
// This array is the same as ...
array(5 => 43, 32, 56, "b" => 12, "a");
```

```
// ...this array
array(5 => 43, 6 => 32, 7 => 56, "b" => 12, 8 =>"a");
?>
```

30

## PHP Types Array

- A **numeric array** stores each array element with a **numeric index**.
- Two methods to create a numeric array
  - `$cars=array("Saab","Volvo","BMW","Toyota");`
  - `$cars[0]="Saab";  
$cars[1]="Volvo";  
$cars[2]="BMW";  
$cars[3]="Toyota";`

31

## PHP Types Array

- An **existing array can be modified** by explicitly setting values in it.
  - This is done by assigning values to the array, specifying the key in brackets. The key can also be omitted.

```
<?php
$arr = array(5 => 1, 12 => 2);
$arr[] = 56;           // This is the same as $arr[13] = 56;
                   // at this point of the script
$arr["x"] = 42;       // This adds a new element to
                   // the array with key "x"
unset($arr[5]);       // This removes the element from the array
unset($arr);           // This deletes the whole array
?>
```

33

## PHP Types Multidimensional Array

- In a **multidimensional array**, each element in the main array can also be an array and each element in the sub-array can be an array, and so on.

```
<?php
$arr = array("somearray" => array(6 => 5, 13 => 9, "a" =>
42));
echo "{$arr["somearray"]}[6]<br>; // 5
echo "{$arr["somearray"]}[13]<br>; // 9
echo "{$arr["somearray"]}[a]<br>; // 42
?>
```

35

## PHP Types Array

```
<?php
$ages = array("Peter"=>32, "Quagmire"=>30, "Joe"=>34);
// or
// $ages['Peter'] = 32;
// $ages['Quagmire'] = 30;
// $ages['Joe'] = 34;
echo "Peter is " . $ages['Peter'] . " years old.";
?>
```

Output: Peter is 32 years old.

32

## PHP Types Array

- To fill an array with **num** entries of the **value** parameter, keys starting at the **start\_index** parameter.

```
array array_fill ( int $start_index , int $num , mixed $value )
If start_index is negative, the first index of the returned array will be
start_index and the following indices will start from zero
<?php
$a = array_fill(5, 6, 'banana');
$b = array_fill(-2, 4, 'pear');
print_r($a);           //displays in a way that's readable by humans
echo '<br>';
print_r($b);
?>
```

```
Array ( [5] => banana [6] => banana [7] => banana [8] =>
banana [9] => banana [10] => banana )
Array ( [-2] => pear [0] => pear [1] => pear [2] => pear )
```

34

34

## PHP Types Array Functions

- array array\_combine (array \$keys , array \$values)** - Creates an array by using the values from the keys array as keys and the values from the values array as the corresponding values.
- array array\_keys ( array \$input [, mixed \$search\_value [, bool \$strict = false ]] )** - Returns the keys, numeric and string, from the input array.
- array array\_merge ( array \$array1 [, array \$array2 [, array \$... ] ] )** - Merges the elements of one or more arrays together so that the values of one are appended to the end of the previous one. It returns the resulting array.
  - If the input arrays have the same string keys, then the later value for that key will overwrite the previous one.
  - If the arrays contain numeric keys, the later value will *not* overwrite the original value, but will be appended.

36

## PHP Types Array Functions

- bool **asort** ( array &\$array [, int \$sort\_flags = SORT\_REGULAR ] )  
- sorts an array such that array indices maintain their correlation with the array elements they are associated with.

```
<?php
$fruits = array("d" => "lemon", "a" => "orange", "b" =>
    "banana", "c" => "apple");
asort($fruits);
foreach ($fruits as $key => $val) {
    echo "$key = $val\n";
}
$num = array (4,2,7,3);
asort($num);
foreach ($num as $key => $val) {
    echo "$key = $val\n";
?
37
```

Output:  
 c = apple  
 b = banana  
 d = lemon  
 a = orange  
 1 = 2  
 3 = 3  
 0 = 4  
 2 = 7

## PHP Types Array Functions

- bool **ksort** ( array &\$array [, int \$sort\_flags = SORT\_REGULAR ] )  
- sorts an array by key, maintaining key to data correlations.

```
<?php
$fruits = array("d"=>"lemon", "a"=>"orange", "b"=>"banana",
    "c"=>"apple");
ksort($fruits);
foreach ($fruits as $key => $val) {
    echo "$key = $val\n";
}
?>
39
```

Output:  
 a = orange  
 b = banana  
 c = apple  
 d = lemon

## PHP Types Array Functions

```
$city = "San Francisco";
$state = "CA";
$event = "SIGGRAPH";
$location_vars = array("city", "state");
$result = compact("event", "nothing_here", $location_vars);
print_r($result);
$var_array = array("color" => "blue",
    "size" => "medium", "shape" => "sphere");
extract($var_array);
echo "<br>$color, $size, $shape\n";
?>
Array ( [event] => SIGGRAPH [city] => San Francisco
    [state] => CA )
    blue, medium, sphere
41
```

## PHP Types Array Functions

- bool **sort** ( array &\$array [, int \$sort\_flags = SORT\_REGULAR ] )  
- sorts an array. Elements will be arranged from lowest to highest when this function has completed.

- # SORT\_REGULAR - compare items normally (don't change types)
- # SORT\_NUMERIC - compare items numerically
- # SORT\_STRING - compare items as strings

```
<?php
$fruits = array("lemon", "orange", "banana", "apple");
sort($fruits);
foreach ($fruits as $key => $val) {
    echo "fruits[" . $key . "] = " . $val . "\n";
}
?>
38
```

Output:  
 fruits[0] = apple  
 fruits[1] = banana  
 fruits[2] = lemon  
 fruits[3] = orange

## PHP Types Array Functions

- array compact** ( mixed \$varname [, mixed \$... ] ) - creates an array containing variables and their values. For each of these, compact() looks for a variable with that name in the current symbol table and adds it to the output array such that the variable name becomes the key and the contents of the variable become the value for that key.

- int extract** ( array \$var\_array [, int \$extract\_type = EXTR\_OVERWRITE [, string \$prefix ]] ) - import variables from an array into the current symbol table. Checks each key to see whether it has a valid variable name. It also checks for collisions with existing variables in the symbol table. Returns the number of variables successfully imported.

## PHP Types gettype

```
<?php
$a_bool = TRUE;           // a boolean
$a_str = "foo";           // a string
$a_str2 = 'foo';          // a string
$an_int = 12;              // an integer

echo gettype($a_bool);    // prints out: boolean
echo gettype($a_str);     // prints out: string
// If this is an integer, increment it by four
if (is_int($an_int)) {   $an_int += 4; }

// If $a_bool is a string, print it out (does not print out anything)
if (is_string($a_bool)) { echo "String: $a_bool";}
?>
42
```

## PHP Types settype

- To forcibly convert a variable to a certain type, either cast the variable or use the `settype()` function on it. It is forbidden to convert a variable to NULL or resource types.

```
<?php
$foo = "5bar";      // string
$bar = true;         // boolean

settype($foo, "integer"); // $foo is now 5 (integer)
settype($bar, "string"); // $bar is now "1" (string)
?>
```

43

## Variable scope Accessing Global Variables

Two ways for accessing global variables.

- Use of global keyword**

```
<?php
$a = 1;
$b = 2;
function sum()
{
    global $a, $b;
    $b = $a + $b;
}
sum();
echo $b;
?>
```

- Note: The above script will output 3.

45

## Variable scope Static Variables

- A static variable exists only in a local function scope, but it does not lose its value when program execution leaves this scope.

```
<?php
function test()
{
    static $a = 0;
    echo $a;
    $a++;
}
?>
```

- \$a is initialized only in the first call of the function and, every time the `test()` function is called, it will print the value of \$a and increment it.

47

## Variable scope

- Any variable used inside a function is by default limited to the local function scope

```
<?php
$a = 1;          /* global scope */
function test()
{
    echo $a;      /* reference to local scope variable */
}
test();
?>
```

- Note: This script will not produce any output because the echo statement refers to a local version of the \$a variable (undefined variable)

44

## Variable scope Accessing Global Variables

- Use of the special PHP-defined \$GLOBALS array**

```
<?php
$a = 1;
$b = 2;
function Sum()
{
    $GLOBALS['b'] = $GLOBALS['a'] + $GLOBALS['b'];
}
Sum();
echo $b;
?>
```

- The \$GLOBALS array is an associative array with the name of the global variable being the key and the contents of that variable being the value of the array element.

46

## Predefined Variable Superglobals

- Superglobals are built-in variables that are always available in all scopes

- \$GLOBALS** — References all variables available in global scope
- \$\_SERVER** — an array containing server and execution environment information (headers, paths and script locations)
- \$\_GET** — An associative array of variables passed to the current script via the URL parameters
- \$\_POST** — An associative array of variables passed to the current script via the HTTP POST method.
- \$\_FILES** — An associative array of items uploaded to the current script via the HTTP POST method.
- \$\_REQUEST** — An associative array that by default contains the contents of \$\_GET, \$\_POST and \$\_COOKIE
- \$\_SESSION** — An associative array containing session variables available to the current script.

48

## Predefined Variable Superglobals

- **`$_ENV`** — An associative array of variables passed to the current script via the environment method (provided by the shell under which PHP is running)
- **`$_COOKIE`** — An associative array of variables passed to the current script via HTTP Cookies
- **`$php_errormsg`** — `$php_errormsg` is a variable containing the text of the last error message generated by PHP. This variable will only be available within the scope in which the error occurred, and only if the `track_errors` configuration option is turned on (it defaults to off)
- **`$HTTP_RAW_POST_DATA`** — Raw POST data
- **`$http_response_header`** — HTTP response headers
- **`$argc`** — The number of arguments passed to script when running from the command line – `php script.php arg1 arg2`
- **`$argv`** — Array of arguments passed to the script

49

## References

Function `unset()` allows separating the variable from its reference

```
<?php
$a = 1000;
$b =& $a;
$b = 50;
echo "$b<br>";    //50
echo "$a<br>";    //50
unset($b);
$a = 0;
echo "$a<br>";    //0
echo "$b<br>";    //The variable is undefined
?>
```

51

## Constants

Name	Description
<code>LINE_</code>	The current line number of the file.
<code>_FILE_</code>	The full path and filename of the file. If used inside an include, the name of the included file is returned.
<code>_DIR_</code>	The directory of the file. If used inside an include, the directory of the included file is returned.
<code>_FUNCTION_</code>	The function name. The constant returns the function name as it was declared (case-sensitive).
<code>_CLASS_</code>	The class name. The constant returns the class name as it was declared (case-sensitive).
<code>_METHOD_</code>	The class method name. (Added in PHP 5.0.0) The method name is returned as it was declared (case-sensitive).

53

## References

- By default, **variables are always assigned by value**.
- PHP also offers another way to assign values to variables: **assign by reference**.

```
<?php
$foo = 'Bob';
$bar = &$foo;
$bar = "My name is $bar";
echo $bar;
echo $foo;
?>
```

- There are three basic operations performed using references: **assigning by reference, passing by reference, and returning by reference**.

50

## Constants

- A **valid constant name** starts with a letter or underscore, followed by any number of letters, numbers, or underscores.

```
<?php
define("FOO",    "something");
define("FOO2",   "something else");
define("FOO_BAR", "something more");
?>
```

- PHP provides a large number of predefined constants to any script which it runs.

52

## PHP Operators

- The PHP operators are practically equal to the C++ operators.
- In the following, we will show only the main differences

54

## PHP Operators Comparison Operators

- We show only the particularities

Example	Name	Result
<code>\$a == \$b</code>	Equal	TRUE if \$a is equal to \$b.
<code>\$a === \$b</code>	Identical	TRUE if \$a is equal to \$b, and they are of the same type. (introduced in PHP 4)
<code>\$a != \$b</code>	Not equal	TRUE if \$a is not equal to \$b.
<code>\$a &lt;&gt; \$b</code>	Not equal	TRUE if \$a is not equal to \$b.
<code>\$a !== \$b</code>	Not identical	TRUE if \$a is not equal to \$b, or they are not of the same type. (introduced in PHP 4)

55

## PHP Operators Execution Operators

- PHP supports one execution operator: backticks (` `). Note that these are not single-quotes!
- PHP will attempt to execute the contents of the backticks as a shell command; the output will be returned (i.e., it won't simply be dumped to output; it can be assigned to a variable).

■ Use of the backtick operator identical to shell\_exec().

```
<?php
// $output = `ls -al`;
//           Unix
// $output = `dir`;
echo "<pre>$output</pre>";
?>
```

The backtick operator is disabled when safe mode is enabled or shell\_exec() is disabled.

57

## PHP Operators Array Operators

Example	Name	Result
<code>\$a + \$b</code>	Union	Union of \$a and \$b.
<code>\$a == \$b</code>	Equality	TRUE if \$a and \$b have the same key/value pairs.
<code>\$a === \$b</code>	Identity	TRUE if \$a and \$b have the same key/value pairs in the same order and of the same types.
<code>\$a != \$b</code>	Inequality	TRUE if \$a is not equal to \$b.
<code>\$a &lt;&gt; \$b</code>	Inequality	TRUE if \$a is not equal to \$b.
<code>\$a !== \$b</code>	Non-identity	TRUE if \$a is not identical to \$b.

The + operator returns the right-hand array appended to the left-hand array; for keys that exist in both arrays, the elements from the left-hand array will be used, and the matching elements from the right-hand array will be ignored.

```
var_dump($a + $b); // bool(true)
var_dump($a === $b); // bool(false)
//var_dump displays structured information
```

59

## PHP Operators Error Control Operators

- PHP supports one error control operator: the at sign (@). When prepended to an expression in PHP, any error messages that might be generated by that expression will be ignored.
- If the track\_errors feature is enabled, any error message generated by the expression will be saved in the variable \$php\_errormsg.

```
<?php
/* Intentional file error */
$my_file = @file ('non_existent_file');
$value = @$cache[$key];
// will not issue a notice if the index $key doesn't exist.
?>
```

56

## PHP Operators Logical Operators

Example	Name	Result
<code>\$a and \$b</code>	And	TRUE if both \$a and \$b are TRUE.
<code>\$a or \$b</code>	Or	TRUE if either \$a or \$b is TRUE.
<code>\$a xor \$b</code>	Xor	TRUE if either \$a or \$b is TRUE, but not both.
<code>! \$a</code>	Not	TRUE if \$a is not TRUE.
<code>\$a &amp;&amp; \$b</code>	And	TRUE if both \$a and \$b are TRUE.
<code>\$a    \$b</code>	Or	TRUE if either \$a or \$b is TRUE.

- The two different variations of "and" and "or" operate at different precedences:

■ <code>\$e = false    true;</code>	// Acts like: (\$e = (false    true))
■ <code>\$f = false or true;</code>	// Acts like: (((\$f = false) or true)

58

## PHP Operators Type Operators

- instanceof is used to determine whether a PHP variable is an instantiated object of a certain class

```
<?php
class MyClass {}
class Not MyClass {}

$a = new MyClass;
var_dump($a instanceof MyClass);
var_dump($a instanceof Not MyClass);
?>

bool(true)
bool(false)
```

60

## PHP Statements

- The PHP statements are practically equal to the C++ statements, except for some particular use:
  - if
  - switch
  - while
  - do-while
  - for
  - break
  - continue

- In the following, we highlight the main differences

61

## PHP Statements For

```
<?php
for ($i=1; $i<=5; $i++) { echo "The number is " . $i . "<br>"; }
?>

<?php
$people = array(
    array('name' => 'Kalle', 'salt' => 856412),
    array('name' => 'Pierre', 'salt' => 215863)
);

for($i = 0, $size = sizeof($people); $i < $size; ++$i)
{
    $people[$i]['salt'] = rand(000000, 999999);
}
print_r($people);
?>

Array ( [0] => Array ( [name] => Kalle [salt] => 64086 )
       [1] => Array ( [name] => Pierre [salt] => 49713 ) )
```

63

## PHP Statements Foreach

- Unless the array is referenced, foreach operates on a copy of the specified array and not the array itself.
- You can easily modify array's elements by preceding \$value with &. This will assign reference instead of copying the value.

```
<?php
$arr = array(1, 2, 3, 4);
foreach ($arr as &$value) {
    $value = $value * 2;
}
// $arr is now array(2, 4, 6, 8)
$value=1000; //Note! $value refers to the last element
print_r($arr); // $arr is now array(2, 4, 6, 1000)
unset($value); // break the reference with the last element
?>
```

65

## PHP Statements

### If

```
if (condition)
    code to be executed if condition is true;
elseif (condition)
    code to be executed if condition is true;
else
    code to be executed if condition is false;

<?php
$d=date("D"); //Returns a string formatted according
               // to the given format string
if ($d=="Fri") echo "Have a nice weekend!";
elseif ($d=="Sun") echo "Have a nice Sunday!";
else echo "Have a nice day!";
?>
```

62

## PHP Statements Foreach

Foreach gives an easy way to iterate over arrays.

- Note: foreach works only on arrays
- Two possible syntaxes (the second is an extension of the first)

**foreach** (array\_expression **as** \$value)  
statement

\ On each loop, the value of the current element is assigned to  
\ \$value and the internal array pointer is advanced by one

**foreach** (array\_expression **as** \$key => \$value)  
statement  
\ On each loop, the current element's key will be assigned to the  
\ variable \$key and the internal array pointer is advanced by one

64

## PHP Statements Break

- break accepts an optional numeric argument which tells it how many nested enclosing structures are to be broken out

```
$i = 0;
while (++$i) {
    switch ($i) {
        case 5:
            echo "At 5<br>";
            break 1; /* Exit only the switch. */
        case 10:
            echo "At 10; quitting<br>";
            break 2; /* Exit the switch and the while. */
        default:
            break;
    }
}
```

66

## PHP Statements Continue

- continue accepts an optional numeric argument which tells it how many levels of enclosing loops it should skip to the end
- Note: continue applies to switch and acts similar to break.

```
$i = 0;
while ($i++ < 5) {
    echo "Outer<br>";
    while (1) {
        echo "&nbsp;&nbsp;Middle<br>";
        while (1) {
            echo "&nbsp;&nbsp;Inner<br>";
            continue 3;
        }
        echo "This never gets output.<br>";
    }
    echo "Neither does this.<br>";
}
```

67

## PHP Statements Alternative syntax

Example:

```
<?php
$a=6;
if ($a == 5):
    echo "a equals 5";
    echo "...";
elseif ($a == 6):
    echo "a equals 6";
    echo "!!!";
else:
    echo "a is neither 5 nor 6";
endif;
?>
```

69

## PHP Statements Include and Require

```
vars.php
<?php
$color = 'green';
$fruit = 'apple';
?>

test.php
<?php
echo "A $color $fruit"; // A
include 'vars.php';
echo "A $color $fruit"; // A green apple
?>
```

71

## PHP Statements Alternative syntax

- PHP offers an alternative syntax for some of its control structures; namely, if, while, for, foreach, and switch.
- The basic form of the alternate syntax is to change the opening brace to a colon (:) and the closing brace to , respectively:
  - endif;
  - endwhile;
  - endfor;
  - endforeach;
  - or endswitch;.

68

## PHP Statements Include and Require

- The include() and require() statements include and evaluate the specified file.
- Files are included based on the file path given or, if none is given, the include\_path specified.
- If the file isn't found in the include\_path, include() and require() will finally check in the calling script's own directory and the current working directory before failing.
- The include() construct will emit a warning if it cannot find a file; this is different behavior from require(), which will emit a fatal error.

70

## PHP Statements Include and Require

- It is possible to execute a return() statement inside an included file in order to terminate processing in that file and return to the script which called it. Also, it's possible to return values from included files.

```
return.php
<?php
$var = 'PHP';
return $var;
?>
```

```
noreturn.php
<?php
$var = 'PHP';
?>
```

72

## PHP Statements Include and Require

```
testreturns.php
<?php
$foo = include 'return.php';
echo "$foo<br>"; // prints 'PHP'
$bar = include 'norelease.php';
echo $bar; // prints 1 (the include was successful)
?>
```

**NOTE:** The `include_once()` and `require_once()` statements include and evaluate the specified file during the execution of the script. This is a behavior similar to the `include()` and `require()` statements, with the only difference being that if the code from a file has already been included, it will not be included again.

73

Francesco Marcelleni

## PHP Functions

- Conditionally defined function

```
<?php
$makefoo = true;
/* We can't call foo() from here since it doesn't exist yet,
but we can call bar() */
bar();
if ($makefoo) {
    function foo()
    { echo "I don't exist until program execution reaches me.\n";
    }
}
/* Now we can safely call foo() since $makefoo evaluated to true */
if ($makefoo) foo();
function bar()
{ echo "I exist immediately upon program start.\n";
?>
```

75

Francesco Marcelleni

## PHP Functions

- All functions and classes in PHP have the **global scope** - they can be called outside a function even if they were defined inside and vice versa.
- PHP does not support **function overloading**, nor is it possible to **undefine** or **redefine** previously-declared functions.
- Function names are **case-insensitive**

77

Francesco Marcelleni

## PHP Functions

- Function definition

```
<?php
function foo($arg_1, $arg_2, /* ... */ $arg_n)
{
    //...
    echo "Example function.\n";
    return $retval;
}
```

- Functions **need not be defined before they are referenced**, except when a function is conditionally defined

74

Francesco Marcelleni

## PHP Functions

- Functions within functions

```
<?php
function foo()
{
    function bar()
    { echo "I don't exist until foo() is called.\n";
    }
}
/* We can't call bar() yet since it doesn't exist.*/
foo();
/* Now we can call bar(), foo()'s processesing has
made it accessible.*/
bar();
?>
```

76

Francesco Marcelleni

## PHP Functions Arguments

- PHP supports passing arguments **by value** (the default), **passing by reference**, and **default argument values**. Variable-length argument lists are also supported

- Passing arrays (by value) to functions

```
<?php
$arr=array(2,3);
takes_array($arr); // 2 + 3 = 5
takes_array($arr); // 2 + 3 = 5
function takes_array($input)
{
    echo "$input[0] + $input[1] = ", $input[0]+$input[1], "<br>";
    $input[0]=10;
}
?>
```

78

Francesco Marcelleni

## PHP Functions Arguments

- Passing arrays (by reference) to functions

```
<?php
$arr=array(2,3);
takes_array($arr);      \\ 2 + 3 = 5
takes_array($arr);      \\ 10 + 3 = 13
function takes_array(&$input)
{
    echo "$input[0] + $input[1] = ", $input[0]+$input[1], "<br>";
    $input[0]=10;
}
?>
```

79

## PHP Functions Arguments

- Default arguments

```
<?php
function makecoffee($type = "cappuccino")
{
    return "Making a cup of $type. <br>";
}
echo makecoffee();          \\ Making a cup of cappuccino.
echo makecoffee(null);     \\ Making a cup of .
echo makecoffee("espresso"); \\ Making a cup of espresso.
?>
```

The **default value must be a constant expression**, not (for example) a variable, a class member or a function call.

81

## PHP Functions Arguments

- PHP 4 and above has support for variable-length argument lists in user-defined functions.

- This is really quite easy, using the func\_num\_args(), func\_get\_arg(int), and func\_get\_args() functions.

```
<?php
function foo()
{
    $numargs = func_num_args();
    echo "Number of arguments: $numargs<br>";
    $arg_list = func_get_args();
    for ($i = 0; $i < $numargs; $i++) {
        echo "Argument $i is: " . $arg_list[$i] . "<br>"; }
}
foo(1, 2, 3);
?>
```

Number of arguments: 3  
Argument 0 is: 1  
Argument 1 is: 2  
Argument 2 is: 3

83

## PHP Functions Arguments

- Passing strings (by value) to functions

```
<?php
function add_some_extra($string)
{
    $string .= 'and something extra.';
}
$str = 'This is a string, ';
add_some_extra($str);
echo $str; // outputs 'This is a string, '
```

- Passing strings (by reference) to functions

```
<?php
function add_some_extra(&$string)
//..
echo $str; // outputs 'This is a string, and something extra.'
```

80

## PHP Functions Arguments

- Note that when using default arguments, **any defaults should be on the right side of any non-default arguments**; otherwise, things will not work as expected.

```
<?php
function makeyogurt($type = "acidophilus", $flavour)
{
    return "Making a bowl of $type $flavour.\n";
}
echo makeyogurt("raspberry"); // won't work as expected
?>
```

**Warning:** Missing argument 2 for makeyogurt(), called in c:\tia\www\php34.php on line 16 and defined in c:\tia\www\php34.php on line 11

Making a bowl of raspberry .

82

## PHP Functions Returning values

- Values are returned by using the optional **return statement**.

- Any type may be returned, including arrays and objects.

```
<?php
function small_numbers()
{
    return array (0, 1, 2);
}
$arr = small_numbers();
print_r($arr);
?>
```

Array ( [0] => 0 [1] => 1 [2] => 2 )

84

## PHP Functions

### Variable Functions

- If a variable name has parentheses appended to it, PHP will look for a function with the same name as whatever the variable evaluates to, and will attempt to execute it.

```
<?php
function foo() { echo "In foo()<br>";}
function bar($arg = "")
{ echo "In bar(); argument was '$arg'.<br>";}
// This is a wrapper function around echo
function echoit($string) { echo $string;}
$func = 'foo';
$func();           // This calls foo()
$func = 'bar';
$func('test');    // This calls bar()
$func = 'echoit';
$func('test');    // This calls echoit()
?>
```

85

## PHP Functions

### Date/Time Functions

- string date ( string \$format [, int \$timestamp ] )**

Returns a string formatted according to the given format string using the given integer timestamp (the number of seconds since January 1 1970 00:00:00 UTC) or the current time if no timestamp is given.

Format character	Description	Example returned values
d	Day of the month, 2 digits with leading zeros	01 to 31
D	A textual representation of a day, three letters	Mon through Sun
j	Day of the month without leading zeros	1 to 31
I (lowercase 'L')	A full textual representation of the day of the week	Sunday through Saturday
...	...	...

87

## PHP Functions

### Date/Time Functions

- array getdate ([ int \$timestamp = time() ] )**

Returns an associative array containing the date information of the timestamp, or the current local time if no timestamp is given.

The keys to access to the values are: seconds, minutes, hours, mday, wday, mon, year,yday, weekday (full text representation of the day of the week), month (full textual representation of a month).

- int time ( void )**

Returns the current time measured in the number of seconds since the Unix Epoch (January 1 1970 00:00:00 GMT).

89

## PHP Functions

### Built-in Functions

- In PHP, there are more than 700 built-in functions.
- Functions are organized in categories in the function reference.
- For instance:
  - Affecting PHP's Behaviour
  - Audio Formats Manipulation
  - Authentication Services
  - Date and Time Related Extensions
  - Compression and Archive Extensions

86

## PHP Functions

### Date

The timestamp can be fixed by using function

- int strtotime ( string \$time [, int \$now ] )**
- Parse about any English textual datetime description into a Unix timestamp

```
<?php
echo date("F j, Y, g:i a") . "<br>";      // January 7, 2011, 1:02 pm
echo date("m.d.y") . "<br>";                // 01.07.11
echo date("j, n, Y") . "<br>";              // 7, 1, 2011
echo date("Ymd") . "<br>";                  // 20110107
echo date("F j, Y, g:i a", strtotime("10 September 2000")) . "<br>";
                                              // September 10, 2000, 12:00 am
echo date("m.d.y") . "<br>";                // 01.07.11
echo date("F j, Y, g:i a", strtotime("+1 day")) . "<br>";
                                              // January 8, 2011, 1:02 pm
?>
```

88

## PHP Functions

### FileSystem Functions

- resource fopen ( string \$filename , string \$mode [, bool \$use\_include\_path = false [, resource \$context ]] )**
- fopen() binds a named resource, specified by filename, to a stream.
- If *filename* is of the form "scheme://...", it is assumed to be a URL and PHP will search for a protocol handler (also known as a wrapper) for that scheme.
- If PHP has decided that filename specifies a local file, then it will try to open a stream on that file.
- If PHP has decided that filename specifies a registered protocol, and that protocol is registered as a network URL, PHP will check to make sure that allow\_url\_fopen is enabled.
- Modes: 'r', 'r+', 'w', 'w+', 'a', 'a+'.  
'+' indicates reading and writing

90

## PHP Functions FileSystem Functions

- **bool copy ( string \$source , string \$dest )**  
Makes a copy of the file source to dest.
- **array file ( string \$filename )**  
Reads an entire file into an array. Each element of the array corresponds to a line in the file, with the newline still attached.
- **bool flock ( resource \$handle , int \$operation )**  
allows you to perform a simple reader/writer model which can be used on virtually every platform(all accessing programs have to use the same way of locking)  
**handle** - A file system pointer resource that is typically created using fopen().  
**operation** is one of the following:  
\* LOCK\_SH to acquire a shared lock (reader).  
\* LOCK\_EX to acquire an exclusive lock (writer).  
\* LOCK\_UN to release a lock (shared or exclusive).

91

## PHP Functions FileSystem Functions

```
<?php
$fp = fopen("lock.txt", "r+");
if (flock($fp, LOCK_EX)) {           // do an exclusive lock
    ftruncate($fp, 0);                // truncate file
    fwrite($fp, "Write something here\n");
    flock($fp, LOCK_UN);             // release the lock
}
else { echo "Couldn't get the lock!";}
fclose($fp);
$fp = fopen("lock.txt", "r");
echo fread($fp, filesize('lock.txt'));// Write something here
fclose($fp);
?>
```

Write something here

93

## PHP Functions Regular Expressions

Some examples of modifiers

- **i** - letters in the pattern match both upper and lower case letters
- **A** - If this modifier is set, the pattern is forced to be "anchored", that is, it is constrained to match only at the start of the string which is being searched (the "subject string").
- **s** - If this modifier is set, a dot metacharacter in the pattern matches all characters, including newlines. Without it, newlines are excluded.

95

## PHP Functions FileSystem Functions

- **int fwrite ( resource \$handle , string \$string [, int \$length ] )**  
writes the contents of string to the file stream pointed to by handle.
- **string fread ( resource \$handle , int \$length )**  
reads up to length bytes from the file pointer referenced by handle. Reading stops as soon as one of the following conditions is met:
  - length bytes have been read
  - EOF (end of file) is reached
  - a packet becomes available or the socket timeout occurs (for network streams)
  - 8192 bytes have been read (after opening userspace stream)

92

## PHP Functions Regular Expressions

- A regular expression is a pattern that is matched against a subject string from left to right. Most characters stand for themselves in a pattern, and match the corresponding characters in the subject.
- The expression must be enclosed in the delimiters, a forward slash (/), for example. Delimiters can be any non-alphanumeric, non-whitespace ASCII character except the backslash (\) and the null byte.
- The ending delimiter may be followed by various modifiers that affect the matching.

94

## PHP Functions Regular Expressions

Some functions

- **int preg\_match ( string \$pattern , string \$subject [, array &\$matches )**  
Searches \$subject for a match to the regular expression given in \$pattern.  
If matches is provided, then it is filled with the results of search.
- **int preg\_match\_all ( string \$pattern , string \$subject [, array &\$matches )**  
Searches subject for all matches to the regular expression given in pattern
- **array preg\_split ( string \$pattern , string \$subject )**  
Split the given string by a regular expression. The function returns an array containing substrings of subject split along boundaries matched by pattern

96

## PHP Functions Regular Expressions

```
<?php
/* The \b in the pattern indicates a word boundary, so only the
distinct word "the" is matched */
$str="PHP is the scripting language of the web.";
if (preg_match("/\bthe\b/i", $str,$output)) {
    echo "A match was found.<br>"; print_r($output);
} else { echo "A match was not found.";}
if (preg_match_all("/\bthe\b/i", $str,$output)) {
    echo "<br>A match was found.<br>"; print_r($output);
} else { echo "A match was not found.";}
echo "<br>";
$result=preg_split("/[\s,]+/", $str);
if ($result) print_r($result);
?>
```

97

## PHP Functions Regular Expressions

## Output

A match was found.  
Array ( [0] => the )  
A match was found.  
Array ( [0] => Array ( [0] => the [1] => the ) )  
Array ( [0] => PHP [1] => is [2] => the [3] => scripting [4] => language [5] => of [6] => the [7] => web. )

98

## PHP Functions Other Functions

- **mixed print\_r ( mixed \$expression )**

**print\_r** — Prints human-readable information about a variable

```
<pre>
<?php
$a = array ('a' => 'apple', 'b' => 'banana', 'c' => array ('x', 'y', 'z'));
print_r ($a);
?>
</pre>
```

99

## PHP Classes

- **Syntax equal to Java**
- The **visibility** of a property or method can be defined by prefixing the declaration with the keywords **public**, **protected** or **private**.
- This declaration may include an initialization, but this initialization must be a constant value (that is, evaluated at compile time)
- Methods declared without any explicit visibility keyword are defined as **public**.
- PHP 5 allows developers to declare constructor methods for classes.

101

## PHP Classes Constructors and Destructors

```
class MyDestructableClass {
    private $name="Default";
    function __construct() {
        print "In constructor\n";
        $this->name .= "MyDestructableClass";
    }
    function __destruct() {
        print "Destroying " . $this->name . "\n";
    }
}
$obj = new MyDestructableClass;
?>
```

In constructor  
Destroying Default: MyDestructableClass

102

## PHP Classes

- **NOTE:** For backwards compatibility, if PHP 5 cannot find a `__construct()` function for a given class, it will search for the old-style constructor function, by the name of the class.
- **NOTE:** `$this` is not a pointer but rather a reference
- **NOTE:** if we do not desire to receive error alerts when using new, adopt the operator `@`, that is, `@new`

103

## PHP Classes

```
<?php
class Stack {
    private $top, $vett;
    function Stack() {
        print "In Stack\n";
        $this->top = -1;
    }
    function push($elem) {
        $this -> vett[++$this->top] = $elem;
    }
}
```

104

## PHP Classes

```
function pop() {
    if ($this->top > -1)
        return $this -> vett[$this->top--];
    return null;
}
$mystack = new Stack;
$mystack->push(15);
echo $mystack->pop()."<br>";
echo $mystack->pop()."<br>";
?>
```

In Stack 15

105

## PHP Classes Inheritance

```
$foo = new Foo();
$bar = new Bar();
$foo->printItem('baz'); // Output: 'Foo: baz'
$foo->printPHP(); // Output: 'PHP is great'
$bar->printItem('baz'); // Output: 'Bar: baz'
$bar->printPHP(); // Output: 'PHP is great'
?>
```

107

## PHP Classes Inheritance

```
class Foo
{
    public function printItem($string)
    {
        echo 'Foo: ' . $string . "<br>";
    }
    public function printPHP()
    {
        echo 'PHP is great.' . "<br>";
    }
}

class Bar extends Foo
{
    public function printItem($string)
    {
        echo 'Bar: ' . $string . "<br>";
    }
}
```

106

## PHP Classes Scope Resolution Operator

```
<?php
class MyClass {
    const CONST_VALUE = 'A constant value';
}
echo MyClass::CONST_VALUE;
?>
```

108

## PHP Classes Scope Resolution Operator

```
<?php
class BaseClass {
    function __construct() {print "In BaseClass constructor<br>"; }
}
class SubClass extends BaseClass {
    function __construct() {
        parent::__construct(); // explicit call
        print "In SubClass constructor <br>";
    }
}
$obj = new BaseClass(); //In BaseClass constructor
$obj = new SubClass(); //In BaseClass constructor
//In SubClass constructor
?>
```

109

## PHP Classes Scope Resolution Operator

```
<?php
class MyClass
{
    protected function myFunc() {
        echo "MyClass::myFunc()<br>";
    }
}
class OtherClass extends MyClass
{
    // Override parent's definition
    public function myFunc()
    {
        // But still call the parent function
        parent::myFunc(); echo "OtherClass::myFunc()<br>";
    }
}
$class = new OtherClass();
$class->myFunc(); //MyClass::myFunc()
//OtherClass::myFunc()
?>
```

110

## PHP Classes Static Keyword

- Declaring class members or methods as **static** makes them accessible without needing an instantiation of the class.
- A member declared as static **can not be accessed with an instantiated class object** (though a method can).

```
<?php
class Foo
{
    public static $my_static = 0;
    public function staticValue() {
        return ++self::$my_static;
    }
}

class Bar extends Foo
{
    public function fooStatic() {
        return ++parent::$my_static;
    }
}
?>
```

111

## PHP Classes Static Keyword

```
print Foo::$my_static . "<br>"; //0

$foo = new Foo();
print $foo->staticValue() . "<br>"; //1
print $foo->my_static . "<br>"; // Undefined "Property" my_static

// $foo::my_static is not possible

print Bar::$my_static . "<br>"; //1
$bar = new Bar();
print $bar->fooStatic() . "<br>"; //2
?>
```

112

## PHP Classes Object Serialization

- **serialize()** returns a string containing a byte-stream representation of any value that can be stored in PHP.
- **unserialize()** can use this string to recreate the original variable values. Using serialize to save an object will save all variables in an object.
- PHP checks if your class has a function with the magic name **\_\_sleep** and will attempt to call it prior to serialization so as to allow the object to do any last minute clean-up, etc. prior to being serialized. Likewise, when the object is restored using unserialize() the **\_\_wakeup** member function is called.

```
<?php
class A {
    public $one = 100;
    public function show_one() { echo $this->one; }
}
?>
```

113

## PHP Classes Object Serialization

```
// page1.php:
include("classe.inc");
$a = new A;
$s = serialize($a);
// store $s somewhere where page2.php can find it.
file_put_contents('store', $s);

// page2.php:
// this is needed for the unserialize to work properly.
include("classe.inc");
$s = file_get_contents('store');
$a = unserialize($s);
// now use the function show_one() of the $a object.
$a->show_one();
```

114

## Forms and User Input

- Any form element in an HTML page will automatically be available to PHP scripts
- The use of the global associative arrays `$_GET`, `$_POST` and `$_REQUEST` allows retrieving information from forms, like user input.
  - `$_GET` - An associative array of variables passed to the current script via the URL parameters.
  - `$_POST` - An associative array of variables passed to the current script via the HTTP POST method.
  - `$_REQUEST` - An associative array that by default contains the contents of `$_GET`, `$_POST` and `$_COOKIE`.

115

## Forms and User Input

```
// file elab.php
<?php
print $_POST['username'];
print $_REQUEST['username'];
?>

<form action="elab.php" method="get">
```

// file elab.php

```
<?php
print $_GET['username'];
print $_REQUEST['username'];
?>
```

117

## Forms and User Input

```
// file elab.php

<?php
import_request_variables('p', 'p_');
print $p_username . "<br>";
print $p_email;
?>
```

119

## Forms and User Input

```
<head>
<title>Form Example</title>
</head>
<body>
<form action="elab.php" method="post">
<p>
Name:<br>
<input type="text" name="username"><br>
E-mail:<br>
<input type="text" name="email"><br>
<input type="submit" name="submit"
value="SUBMIT">
</p>
</form>
</body>
```

116

## Forms and User Input

`bool import_request_variables ( string $types [, string $prefix ] )`

- Imports GET/POST/Cookie variables into the global scope.

- Types parameter** – you can specify which request variables to import. You can use 'G', 'P' and 'C' characters respectively for GET, POST and Cookie. These characters are not case sensitive.
- \$prefix parameter** - is prepended before all variable's name imported into the global scope. So if you have a GET value named "userid", and provide a prefix "pref\_", then you'll get a global variable named \$pref\_userid.

118

## PHP Forms and User Input

### Form Validation

- User input should be validated on the browser whenever possible (by client scripts). Browser validation is faster and reduces the server load.
- You should consider server validation if the user input will be inserted into a database. A good way to validate a form on the server is to post the form to itself, instead of jumping to a different page. The user will then get the error messages on the same page as the form. This makes it easier to discover the error.

120

<p><i>Università di Pisa</i></p>  <h2>Get or Post</h2> <ul style="list-style-type: none"> <li>■ Information sent from a form with the <b>GET method</b> is visible to everyone (it will be displayed in the browser's address bar) and has limits on the amount of information to send (max. 100 characters).</li> <li>■ Information sent from a form with the <b>POST method</b> is invisible to others and has no limits on the amount of information to send.</li> <li>■ However, because the variables are not displayed in the URL, it is not possible to bookmark the page.</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p><i>Università di Pisa</i></p> 	<p><i>Francesco Marcelleni</i></p> <p><b>Cookie</b></p> <ul style="list-style-type: none"> <li>■ A cookie is a small piece of data sent from a website and stored in a user's web browser while the user is browsing that website.</li> <li>■ A web server specifies a cookie to be stored by sending an HTTP header called Set-Cookie.</li> </ul> <p>Set-Cookie: value[; expires=date][; domain=domain][; path=path][; secure]</p> <ul style="list-style-type: none"> <li>■ When a cookie is present, and the optional rules allow, the cookie value is sent to the server with each subsequent request. The cookie value is stored in an HTTP header called Cookie and contains just the cookie value without any of the other options</li> </ul> <p>Cookie: value</p>
<p><i>IN SUPERMÆ DIGNITATIS 1343</i></p> <p>121</p>  <h2>Cookie</h2> <pre>bool setcookie ( string \$name [, string \$value [, int \$expire = 0 [, string \$path [, string \$domain [, bool \$secure = false [, bool \$httponly = false ]]]]]] )</pre> <ul style="list-style-type: none"> <li>■ <b>setcookie()</b> defines a cookie to be sent along with the rest of the HTTP headers. <ul style="list-style-type: none"> <li>■ Like other headers, <b>cookies must be sent before any output from your script</b> (this is a protocol restriction). This requires that you place calls to this function prior to any output, including &lt;html&gt; and &lt;head&gt; tags as well as any whitespace.</li> </ul> </li> </ul>	<p><i>Francesco Marcelleni</i></p> <p><i>IN SUPERMÆ DIGNITATIS 1343</i></p> <p>122</p> 	<p><i>Francesco Marcelleni</i></p> <p><b>Cookie</b></p> <p><b>Expire</b></p> <ul style="list-style-type: none"> <li>■ Indicates when the cookie should no longer be sent to the server and therefore may be deleted by the browser.</li> <li>■ Without the expires option, a cookie has a lifespan of a single session. A session is defined as finished when the browser is shut down, so session cookies exist only while the browser remains open.</li> </ul>
<p><i>IN SUPERMÆ DIGNITATIS 1343</i></p> <p>123</p>  <h2>Cookie</h2> <p><b>Domain</b></p> <ul style="list-style-type: none"> <li>■ Indicates the domain(s) for which the cookie should be sent.</li> <li>■ By default, <b>domain</b> is set to the host name of the page setting the <b>cookie</b>, so the cookie value is sent whenever a request is made to the same host name.</li> <li>■ For example, the default domain for a cookie set might be www.ing.unipi.it.</li> <li>■ The domain option is used to widen the number of domains for which the cookie value will be sent.</li> <li>■ Consider the case of a large network such as Yahoo! that has many sites in the form of name.yahoo.com (e.g., my.yahoo.com, finance.yahoo.com, etc.). A single cookie value can be set for all of these sites by setting the domain option to simply yahoo.com.</li> </ul>	<p><i>Francesco Marcelleni</i></p> <p><i>IN SUPERMÆ DIGNITATIS 1343</i></p> <p>124</p> 	<p><i>Francesco Marcelleni</i></p> <p><b>Cookie</b></p> <p><b>Path</b></p> <ul style="list-style-type: none"> <li>■ Indicates a URL path that must exist in the requested resource before sending the Cookie header. This comparison is done by comparing the option value character-by-character against the start of the request URL. If the characters match, then the Cookie header is sent.</li> </ul> <p>Ex:</p> <p>Set-Cookie: name=Nicholas; path=/blog</p> <ul style="list-style-type: none"> <li>■ The path option would match /blog, /blogroll, etc.; anything that begins with /blog is valid. Note that this comparison is only done once the domain option has been verified. The default value for the path option is the path of the URL that sent the Set-Cookie header.</li> </ul>
<p><i>IN SUPERMÆ DIGNITATIS 1343</i></p> <p>125</p>  <p>163</p>	<p><i>Francesco Marcelleni</i></p> <p><i>IN SUPERMÆ DIGNITATIS 1343</i></p>	<p><i>Francesco Marcelleni</i></p> 

<p><i>Francesco Marcelleni</i></p> <h2>Cookie</h2> <p><b>Secure</b></p> <ul style="list-style-type: none"> <li>just a flag and has no additional value specified. A secure cookie will only be sent to the server when a request is made using SSL and the HTTPS protocol.</li> <li>confidential or sensitive information should never be stored or transmitted in cookies as the entire mechanism is inherently insecure. By default, cookies set over an HTTPS connection are automatically set to be secure.</li> </ul>	<p><i>Francesco Marcelleni</i></p>	<p><i>Francesco Marcelleni</i></p> <h2>Cookie</h2> <pre>&lt;?php \$value = 'something from somewhere'; setcookie("TestCookie", \$value, time() + 3600, "/~rasmus/", ".example.com", 1); /* expire in 1 hour, available within the /~rasmus/ directory and all sub-directories, available on all subdomains of example.com and set if a secure connection exists*/ ?&gt;</pre>
<p><i>Francesco Marcelleni</i></p> <p>127</p>	<p><i>Francesco Marcelleni</i></p>	<p><i>Francesco Marcelleni</i></p> <p>128</p>
<p><i>Francesco Marcelleni</i></p> <h2>Cookie</h2> <p>To see the contents of the test cookie in a script</p> <pre>&lt;?php // Print an individual cookie echo \$_COOKIE["TestCookie"]; // Another way to debug/test is to view all cookies print_r(\$_COOKIE); ?&gt;</pre> <p><b>Output</b></p> <pre>something from somewhere Array ( [TestCookie] =&gt; something from somewhere )</pre>	<p><i>Francesco Marcelleni</i></p>	<p><i>Francesco Marcelleni</i></p> <h2>Cookie</h2> <ul style="list-style-type: none"> <li>Cookies are usually set in an HTTP header (although JavaScript can also set a cookie directly on a browser)</li> </ul> <p>An example of header returned by a PHP program:</p> <pre>HTTP/1.1 200 OK Date: Fri, 04 Feb 2000 21:03:38 GMT Server: Apache/1.3.9 (UNIX) PHP/4.0b3 Set-Cookie: name=xyz; expires=Friday, 04-Feb-07 22:03:38 GMT; path=/; domain=tutorialspoint.com Connection: close Content-Type: text/html</pre>
<p><i>Francesco Marcelleni</i></p> <p>129</p>	<p><i>Francesco Marcelleni</i></p>	<p><i>Francesco Marcelleni</i></p> <p>130</p>
<p><i>Francesco Marcelleni</i></p>	<p><i>Francesco Marcelleni</i></p>	<p><i>Francesco Marcelleni</i></p>
<p><i>Francesco Marcelleni</i></p>	<p><i>Francesco Marcelleni</i></p>	<p><i>Francesco Marcelleni</i></p>

## Cookie

- Example of use of the cookies

```
<html>
<head>
<title>Accessing Cookies with PHP</title>
</head>
<body>
<?php
if( isset($_COOKIE["name"]))
echo "Welcome " . $_COOKIE["name"] . "<br />";
else
echo "Sorry... Not recognized" . "<br />";
?>
</body>
</html>
```

133

## Cookie

- Deleting cookie with PHP

```
<?php
setcookie( "name", "", time()- 60, "/", "", 0);
setcookie( "age", "", time()- 60, "/", "", 0);
?>
<html>
<head>
<title>Deleting Cookies with PHP</title>
</head>
<body>
<?php echo "Deleted Cookies" ?>
</body>
</html>
```

134

## Sessions

- Session support allows preserving certain data across subsequent accesses.
  - This enables you to build more customized applications and increase the appeal of your web site.
- A visitor accessing your web site is assigned a unique id, the so-called **session id**. This is either stored in a cookie on the user side or is propagated in the URL.
- The session support allows you to register arbitrary numbers of variables to be preserved across requests.
  - When a visitor accesses your site, PHP will check automatically (if session.auto\_start is set to 1) or on your request (explicitly through session\_start() or implicitly through session\_register()) whether a specific session id has been sent with the request.
  - If this is the case, the prior saved environment is recreated.

135

## Sessions

```
//page.php
<?php
session_start();
if (!isset($_SESSION['count']))
//Determine if a variable is set and is not NULL.
{ echo "<p>You have to login</p>"; }
else { $_SESSION['count']++;
echo "<p>Hi, you have visited this page " .
$_SESSION['count'] . " times.</p>";
echo "<p>
<a href=\"page.php\">GO</a>, or
<a href=\"logout.php\">Exit</a>.</p>";}
?>
```

137

## Sessions

```
//login.php
<?php
session_start();
$_SESSION['count'] = 0;
?>
<p>Welcome :)<br>
<a href="page.php">GO</a>.
</p>
```

session\_start() creates a session or resumes the current one based on a session identifier passed via a GET or POST request, or passed via a cookie

136

## Sessions

```
//logout.php
<?php
session_start(); unset($_SESSION['count']);
?>
<p>Good Bye :(</p>
```

138

<p>Università di Pisa</p>  <h2>Sessions</h2> <pre>//form.php &lt;!DOCTYPE html&gt; &lt;html lang="en"&gt; &lt;head&gt; &lt;meta charset="utf-8"&gt; &lt;title&gt;Login&lt;/title&gt; &lt;style type="text/css"&gt; p { font-size: 30pt; } &lt;/style&gt; &lt;/head&gt; &lt;body&gt; &lt;form method="post" action="login.php"&gt; &lt;p&gt;Username: &lt;input type="text" name="username"&gt;&lt;/p&gt; &lt;p&gt;Password: &lt;input type="text" name="password"&gt;&lt;/p&gt; &lt;p&gt;&lt;input type="submit" value="Let me in"&gt;&lt;/p&gt; &lt;/form&gt; &lt;/body&gt; &lt;/html&gt;</pre> <p>Francesco Marcelleni</p>	<p>Università di Pisa</p>  <h2>Sessions</h2> <pre>//login.php &lt;!DOCTYPE html&gt; &lt;html lang="en"&gt; &lt;head&gt; &lt;meta charset="utf-8"&gt; &lt;title&gt;Login&lt;/title&gt; &lt;/head&gt; &lt;body&gt; &lt;?php // Check if username and password are correct if (\$_POST["username"] == "php" &amp;&amp; \$_POST["password"] == "php") {</pre> <p>Francesco Marcelleni</p>

## PHP and mysql

```
// Formulate Query
// This is the best way to perform an SQL query
$query = "SELECT * FROM studenti";

// Perform Query
$result = $mysqli->query($query);

/* Check result
   This shows the actual query sent to MySQL, and the error.
   Useful for debugging.*/
checkResult($result,$query);

//show results
showResult($result);
```

151

## PHP and mysql

```
// Free the resources associated with the result set
// This is done automatically at the end of the script
$result->close();
$mysqli->close();

function checkResult($result, $query)
{ if (!$result) {
    $message = 'Invalid query: ' . $mysqli->error . "\n";
    $message .= 'Whole query: ' . $query;
    die($message);
}
}
```

152

## PHP and mysql

```
function showResult($result)
{
    while ($row = $result->fetch_assoc()) {
        echo $row['MATRICOLA']. " ";
        echo $row['NOME'] . "<br>";
    }
    echo "<br>";
?>

1111 ROMOLO
2222 REMO
3333 CESARE
4444 PIPPO
```

`mysqli_result::fetch_assoc()` - Returns an associative array that corresponds to the fetched row and moves the internal data pointer ahead.

153

## PHP and mysql

```
function filterSQLQuery($string) {
    if (get_magic_quotes_gpc())
        /*When magic_quotes are on for GPC (Get/Post/Cookie) operations,
        all ', ", \ and NUL's are escaped with a backslash automatically –
        This feature has been removed in PHP 5.4.0 and the function returns
        always false*/
        $string = stripslashes($string);
        // removes slashes (\)
    if (!is_numeric($string))
        $string = "" . mysqli_real_escape_string($string) . "";
    /*Escapes special characters in a string for use in an SQL statement
    in such a way that the SQL statements are sure;*/
    return $string
}
```

1111 ROMOLO  
3333 CESARE

155

## PHP and mysql

```
$name = 'ROMOLO';
$query = sprintf("SELECT * FROM studenti WHERE NOME =%s",
filterSQLQuery($name));
$result = $mysqli->query($query);
checkResult($result,$query);
showResult($result);

$mat = 3333;
$query = sprintf("SELECT * FROM studenti WHERE MATRICOLA
=%s", filterSQLQuery($mat));
$result = $mysqli->query($query);
checkResult($result,$query);
showResult($result);
```

154

## SQL Injection Attack

- Exploiting SQL code is possible to obtain private information or modify a database

### Esempio

Let us assume to have a login form which asks for username and password.  
These data are used to perform sql query:

```
$miaQuery="SELECT COUNT(*) FROM utenti
WHERE username=' " . $_POST['username']. " '
AND password=' " . $_POST['password']. " '";
```

username	password
----------	----------

156

## SQL Injection Attack

Input the following data:

```
SELECT COUNT(*)
WHERE username='GIANNI'
AND password= '' OR '' = '';
```

The query results to be:

```
SELECT COUNT(*) FROM utenti
WHERE username='GIANNI'
AND password= '' OR '' = '';
```

Same effect as knowing the GIANNI's password. By using `mysql_real_escape_string`, each quote is escaped.

157

## AJAX

- Asynchronous JavaScript and XML (AJAX) is a group of interrelated web development techniques used on the client-side to create interactive web applications.
- With Ajax, web applications can retrieve data from the server asynchronously in the background without interfering with the display and behavior of the existing page.
- Instead of using normal HTTP POST or GET requests (such as when using forms or hyperlinks), data is usually retrieved using the XMLHttpRequest object

159

## AJAX

- **XMLHttpRequest object**
  - used to send HTTP or HTTPS requests directly to a web server and load the server response data directly back into the script.
  - The data might be received from the server as XML text or as plain text.
  - Data from the response can be used directly to alter the DOM of the currently active document in the browser window without loading a new web page document.

161

## SQL Injection Attack

Other examples:

```
SELECT COUNT(*)
WHERE username= '' OR 1=1 --
AND password= '';
```

The text (in italic) after -- is not considered since it indicates an SQL comment. The query will return the number of rows in the table.

158

## AJAX

160

## AJAX

Three steps

- **Create an XMLHttpRequest object**

```
try { xmlhttp=new XMLHttpRequest(); }
catch (e) {
    try { xmlhttp=new ActiveXObject("Msxml2.XMLHTTP"); }
    //IE (recent versions)
    catch (e) {
        try { xmlhttp=new ActiveXObject("Microsoft.XMLHTTP"); }
        //IE (older versions)
        catch (e) {
            window.alert("Your browser does not support AJAX!");
            return false;
        }
    }
}
```

162

## AJAX

- Write an event handler for sending requests for data to the server

```
xmlHttp.open("GET","data.php",true);
xmlHttp.onreadystatechange = useHttpResponse;
xmlHttp.send(null);
```

### open(method,url,async)

Specifies the type of request, the URL, and if the request should be handled asynchronously or not.  
 method: the type of request: GET or POST  
 url: the location of the file on the server  
 async: true (asynchronous) or false (synchronous)

### onreadystatechange

Stores a function (or the name of a function) to be called automatically each time the readyState property changes

163

## AJAX

- Write a function useHttpResponse which will establish when the server has completed the request and will do something useful with the returned data

```
function useHttpResponse() {
  if (xmlHttp.readyState == 4)
    document.myModule.day.value = xmlHttp.responseText;
}
```

### readyState

Holds the status of the XMLHttpRequest. Changes from 0 to 4:  
 0: request not initialized  
 1: server connection established  
 2: request received  
 3: processing request  
 4: request finished and response is ready

165

## AJAX

- Example (submit.html)

```
<html lang="en">
<head>
<meta charset="utf-8">
<title>Example</title>
</head>
<body>
<script type="text/javascript" src="./myajax.js"></script>
<form action="#" name="myModule" id="myModule">
<p>Name: <input type="text" onkeyup="ajaxHandler();"
name="name">
Date: <input type="text" name="day"></p>
</form>
</body>
</html>
```

167

## AJAX

### send(string)

Sends the request off to the server.  
 string: Only used for POST requests

### Example:

```
xmlHttp.open("POST","ajax_test.php",true);
xmlHttp.setRequestHeader("Content-type","application/x-www-form-urlencoded");
xmlHttp.send("fname=Henry&lname=Ford");
```

### setRequestHeader(header,value)

Adds HTTP headers to the request.

header: specifies the header name  
 value: specifies the header value

164

## AJAX

### responseText

get the response data as a string

### responseXML

get the response data as XML data

166

## AJAX

```
\date.php
<?php $oggi = date("D M Y G:i:s"); echo($oggi); ?>

myajax.js
function ajaxHandler() {
  var xmlhttp;
  try { xmlhttp=new XMLHttpRequest(); }
  catch (e) {
    try { xmlhttp=new ActiveXObject("Msxml2.XMLHTTP"); }
    catch (e)
    try { xmlhttp=new ActiveXObject("Microsoft.XMLHTTP"); }
    catch (e)
    {
      window.alert("Your browser does not support AJAX!");
      return;
    }
  }
}
```

168

## AJAX

```

xmlHttp.open("GET", "date.php",true);
xmlHttp.onreadystatechange = useHttpResponse;
xmlHttp.send(null);

function useHttpResponse()
{
    if(xmlHttp.readyState == 4)
        document.mymodule.day.value = xmlHttp.responseText;
}

```

169

## Three-tier architecture UML - Deployment Diagram

171

172

## Three-tier architecture

### Presentation tier

The top-most level of the application is the user interface. The main function of the interface is to translate tasks and results to something the user can understand.

### Logic tier

This tier coordinates the application, processes commands, makes logical decisions and evaluations, and performs calculations. It also moves and processes data between the two surrounding layers.

### Data tier

Here information is stored and retrieved from a database or file system. The information is then passed back to the logic tier for processing, and then eventually back to the user.

170

## Three-tier architecture

- The Common Gateway Interface (CGI) is a standard (see RFC 3875: CGI Version 1.1) that defines how web server software can delegate the generation of web pages to a text-based application.
- CGI is a standard way for a Web server to pass a Web user's request to an application program and to receive data back to forward to the user.
- httpd.conf – configuration file for determining for instance the root
- php.ini – configuration file for selecting the DBMS and the libraries

## Three-tier architecture

- In the web development field, three-tier is often used to refer to websites, commonly electronic commerce websites, which are built using three tiers:
  - A front-end web server serving static content, and potentially some cached dynamic content. In web based application, Front End is the content rendered by the browser. The content may be static or generated dynamically.
  - A middle dynamic content processing and generation level application server, for example Java EE, ASP.NET, PHP platform.
  - A back-end database, comprising both data sets and the database management system or RDBMS software that manages and provides access to the data.

173

## Designing Web Applications

### HTTP

## HTTP Overview

### First some jargon

- Web page consists of **objects**
- Objects can be HTML files, JPEG images, Java applets, audio files,...
- Web page consists of **base HTML-file** which includes several referenced objects
- Each object is addressable by a **URI**
- Example URI:

[www.someschool.edu/someDept/pic.gif](http://www.someschool.edu/someDept/pic.gif)

host name

path name

4

## HTTP Overview

### HTTP: hypertext transfer protocol

- Web's application layer protocol
- client/server model
  - **client**: browser that requests, receives, "displays" Web objects
  - **server**: Web server sends objects in response to requests

6

## HTTP Overview

### Uses TCP:

- client initiates TCP connection (creates socket) to server, port 80
- server accepts TCP connection from client
- HTTP messages (application-layer protocol messages) exchanged between browser (HTTP client) and Web server (HTTP server)
- TCP connection closed

### HTTP is "stateless"

- server maintains no information about past client requests

**Protocols that maintain "state" are complex!**

- past history (state) must be maintained
- if server/client crashes, their views of "state" may be inconsistent, must be reconciled

aside

7

8

## HTTP Connections

### Nonpersistent HTTP

- At most one object is sent over a TCP connection.

### Persistent HTTP

- Multiple objects can be sent over single TCP connection between client and server.

## Nonpersistent HTTP

### Suppose user enters URL

(contains text, references to 10 jpeg images)  
www.someSchool.edu/someDepartment/home.index

- 1a. HTTP client initiates TCP connection to HTTP server (process) at www.someSchool.edu on port 80
- 1b. HTTP server at host www.someSchool.edu waiting for TCP connection at port 80. "accepts" connection, notifying client
2. HTTP client sends HTTP *request message* (containing URL) into TCP connection socket. Message indicates that client wants object someDepartment/home.index
3. HTTP server receives request message, forms *response message* containing requested object, and sends message into its socket

9

10

## Nonpersistent HTTP (continued)

4. HTTP server closes TCP connection.
5. HTTP client receives response message containing html file, displays html. Parsing html file, finds 10 referenced jpeg objects
6. Steps 1-5 repeated for each of 10 jpeg objects

10

## Nonpersistent HTTP (continued)

11

## Nonpersistent HTTP: Response Time

**Definition of Round-Trip Time (RTT):** time for a small packet to travel from client to server and back.

### Response time:

- one RTT to initiate TCP connection
  - one RTT for HTTP request and first few bytes of HTTP response to return
  - file transmission time
- total = 2RTT+transmit time

12

## Persistent HTTP

### Nonpersistent HTTP issues:

- requires 2 RTTs per object
- OS overhead for *each* TCP connection (for each connection, TCP buffers and TCP variables have to be allocated in the client and in the server)
- browsers often open parallel TCP connections to fetch referenced objects

### Persistent HTTP

- server leaves connection open after sending response
- subsequent HTTP messages between same client/server sent over open connection
- Pipelining version:
  - client sends requests as soon as it encounters a referenced object
  - as little as one RTT for all the referenced objects

13

14

## Persistent HTTP

### With pipelining (default mode in HTTP/1.1)

- The client issues a new request as soon as it encounters a reference.
- It is possible for only one RTT to be expended for all the referenced objects
- The pipelined TCP connection remains idle for a smaller fraction of time

15

16

## Persistent HTTP

Without Pipelining

With Pipelining

## HTTP Request Message

- two types of HTTP messages: *request, response*
- **HTTP request message:**

- ASCII (human-readable format)

request line  
(HTTP commands)

```
GET /somedir/page.html HTTP/1.1
Host: www.someschool.edu
User-agent: Mozilla/4.0
Connection: close
Accept-language:fr
```

header lines

(extra carriage return, line feed)

Carriage return,  
line feed  
indicates end  
of message

17

## HTTP Request Message

### Connection: close

- The browser is telling the server that it does not want to use persistent connections (when it wants, it uses Keep-Alive)

### User-agent

- Specifies the user agent, that is, the browser that is making the request to the server
- Useful: the server could send different versions of the same object to different types of user agent

### Accept-language

- The user prefers to receive a French version of the object, if such an object exists on the server; otherwise the server should send its default version

18

## HTTP Request Message General Format

19

## HTTP Request Message

### HTTP/1.0

- GET
- POST
- HEAD
  - asks server to leave requested object out of response

### HTTP/1.1

- GET, POST, HEAD
- PUT
  - uploads file in entity body to path specified in URL field
- DELETE
  - deletes file specified in the URL field
- TRACE
  - invoke a remote, application-layer loop-back of the request message

21

## HTTP Request Message

- POST
  - The URI specifies the script which should process the information
  - The entity body contains what the user entered into the form fields
  - The script is called at each form submission (no cache)

23

## HTTP Request Message

- Web page often include form input

### Post method:

- Input is uploaded to server in entity body

### GET method:

- Input is uploaded in URL field of request line:

[www.somesite.com/animalsearch?monkeys&banana](http://www.somesite.com/animalsearch?monkeys&banana)

20

## HTTP Request Message

### GET

- Input in the URL field. No entity body
- Safe and idempotent (the side-effects of  $N > 0$  identical requests is the same as for a single request)
- Only ASCII characters
- Browser and proxy can cache the responses of the server

22

## HTTP Request Message

### HEAD

- Similar to the GET method
- When a server receives a request with the HEAD method, it responds with an HTTP message but it leaves out the requested object
- Often used for debugging

24

## HTTP Request Message

### ■ PUT

- Used in conjunction with Web publishing tools
- Allows a user to upload an object to a specific path (directory) on a specific Web server (typically the object is a file)
- If the Request-URI refers to an already existing resource, the enclosed entity SHOULD be considered as a modified version of the one residing on the origin server.
- Used by applications which need to upload objects to Web servers

## HTTP Request Message

### ■ DELETE

- Allows a user, or an application, to delete an object on a Web server

26

## HTTP Request Message

### ■ TRACE

- The TRACE method is used to invoke a remote, application-layer loop-back of the request message.
- The final recipient (origin server or proxy) of the request SHOULD reflect the message received back to the client as the entity-body of a 200 (OK) response.
- TRACE allows the client to see what is being received at the other end of the request chain and use that data for testing or diagnostic information.

27

## HTTP Request Message

### ■ TRACE (example)

28

## HTTP Request Message

### ■ TRACE (example)

29

## HTTP Request Message

### ■ TRACE (example)

30

## HTTP Request Message

- TRACE (example)

④

```
HTTP/1.1 200 OK
Date: Tue, 21 May 2002 12:34:56 GMT
Server: Apache/1.3.22 (Unix)
Content-Type: message/http

TRACE / HTTP/1.1
Host: webserver.localdomain
Via: 1.1 proxya.localdomain, 1.1proxyb.localdomain
```

31

## HTTP Request Message

- TRACE (example)

⑥

```
HTTP/1.1 200 OK
Date: Tue, 21 May 2002 12:34:56 GMT
Server: Apache/1.3.22 (Unix)
Content-Type: message/http
Via: 1.1 proxyb.localdomain, 1.1 proxya.localdomain

TRACE / HTTP/1.1
Host: webserver.localdomain
Via: 1.1 proxya.localdomain, 1.1proxyb.localdomain
```

33

## HTTP Response Status Codes

In first line in server->client response message.

A few sample codes:

**200 OK**

- request succeeded, requested object later in this message

**301 Moved Permanently**

- requested object moved, new location specified later in this message (Location:)

**400 Bad Request**

- request message not understood by server

**404 Not Found**

- requested document not found on this server

**505 HTTP Version Not Supported**

35

## HTTP Request Message

- TRACE (example)

⑤

```
HTTP/1.1 200 OK
Date: Tue, 21 May 2002 12:34:56 GMT
Server: Apache/1.3.22 (Unix)
Content-Type: message/http
Via: 1.1 proxyb.localdomain

TRACE / HTTP/1.1
Host: webserver.localdomain
Via: 1.1 proxya.localdomain, 1.1proxyb.localdomain
```

32

## HTTP Response Message

status line  
(protocol,  
status code,  
status phrase)

header  
lines

data, e.g.,  
requested  
HTML file

HTTP/1.1 200 OK  
Connection close  
Date: Thu, 06 Aug 1998 12:00:15 GMT  
Server: Apache/1.3.0 (Unix)  
Last-Modified: Mon, 22 Jun 1998 .....  
Content-Length: 6821  
Content-Type: text/html

data data data data data ...

34

## HTTP Response Message Header Lines

- **Date:** indicates the time and the date when the HTTP response was created and sent by the server
- **Content-Type:** indicates that the object in the entity body is HTML text (The object type is officially indicated by the Content-Type: header and not by the file extension)

36

## Trying HTTP

### 1. Telnet to your favorite Web server:

```
telnet localhost 80
```

Opens TCP connection to port 80 (default HTTP server port) at localhost. Anything typed in sent to port 80 at localhost

### 2. Type in a GET HTTP request:

```
GET /form.html HTTP/1.1
Host: localhost
```

By typing this in (hit carriage return twice), you send this minimal (but complete) GET request to HTTP server

### 3. Look at response message sent by HTTP server!

37

## Trying HTTP

```
/* Redirect to a different page in the current directory that was
requested */
<?php
    $host = $_SERVER['HTTP_HOST'];
    $uri = rtrim(dirname($_SERVER['PHP_SELF']), '\\');
    //rtrim — Strip whitespace (or other characters) from the
    end of a string
    $extra = 'receiveGET.php?name=Bob&age=21';
    header("Location: http://$host$uri$extra");
    //Send a raw HTTP header
    exit;
?>
</body>
</html>
```

39

## Trying HTTP (post.php)

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN"
"http://www.w3.org/TR/html4/strict.dtd">
<html lang="en">
<head>
<meta http-equiv="Content-type" content="text/html;
charset=ISO-8859-1">
<title>send data using the POST method without forms and
opening a new page</title>
</head>
<body>
<p>
```

41

## Trying HTTP (get.php)

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN"
"http://www.w3.org/TR/html4/strict.dtd">
<html lang="en">
<head>
<meta http-equiv="Content-type" content="text/html;
charset=ISO-8859-1">
<title>send data using the GET method without forms and
opening a new page</title>
</head>
<body>
```

38

## Trying HTTP (receiveGet.php)

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN"
"http://www.w3.org/TR/html4/strict.dtd">
<html>
<head>
<meta http-equiv="Content-Type" content="text/html;
charset=iso-8859-1">
<title>Receive data and forward to the client</title>
</head>
<body>
<p> Hi <?php echo htmlspecialchars($_GET['name']); ?>,<br>
    You are <?php echo (int)$_GET['age']; ?> old.
</p>
</body>
</html>
```

**htmlspecialchars — Convert special characters to HTML entities**

40

## Trying HTTP (post.php)

```
<?php
$data =
sendPost('/receivePOST.php','name=Bob&age=21','localhost');
echo $data;

function sendPost($uri,$postdata,$host){
    $flow = fsockopen($host, 80, $errno, $errstr);
    //Initiates a socket connection to the resource specified by
    hostname.
    if (!$flow) {
        echo "$errstr ($errno)  
\n";
        echo $flow;      }
    else {
```

42

## Trying HTTP (post.php)

```
$requestHTTP = "POST $uri HTTP/1.1\r\n";
$requestHTTP.= "Host: $host\r\n";
$requestHTTP.= "User-Agent: PHP Script\r\n";
$requestHTTP.= "Content-Type: application/x-www-form-
    urlencoded\r\n";
$requestHTTP.= "Content-Length: ".strlen($postdata)."\r\n";
$requestHTTP.= "Connection: close\r\n\r\n";
$postdata;
$replyHTTP = NULL;
fwrite($flow, $requestHTTP);
while (!feof($flow))
    $replyHTTP.= fgets($flow, 128);
$replyHTTP = explode("\r\n\r\n", $replyHTTP);
$headerReplyHTTP = $replyHTTP[0];
$contentsReplyHTTP = $replyHTTP[1];
43
```

## Trying HTTP (post.php)

```
if(!(strpos($headerReplyHTTP,"Transfer-Encoding:
    chunked") === false))
{
    $temp=explode("\r\n", $contentsReplyHTTP);
    for($i=0;$i<count($temp);$i++)
        if($i==0 || ($i%2==0))
            $temp[$i]="";
    $contentsReplyHTTP=implode("", $temp);
    //implode — Join array elements with a string
}
fclose($flow);
return rtrim($contentsReplyHTTP);
}
}?
</p>
</body>
</html>
```

44

## Trying HTTP (receivePost.php)

Example of chunked transfer-encoding

HTTP/1.1 200 OK  
 Content-Type: text/plain  
 Transfer-Encoding: chunked  
 25\r\n  
 This is the data in the first chunk\r\n  
 1C\r\n  
 and this is the second one\r\n  
 3\r\n  
 Con\r\n  
 8\r\n  
 Sequence\r\n  
 0\r\n

45

## Header Lines

- How does a browser decide which header lines to include in a request message?
  - Browser type and version
  - User configuration of the browser
  - If the browser has a cached, but possibly out-of-date version of the object
- How does a Web server decide which header lines to include in a response message?
  - Server type and version
  - Server configuration

47

48

## Header Lines

- HTTP/1.0 defines 16 different header lines (no mandatory)
- HTTP/1.1 defines 51 different header lines (only one Host is mandatory) in the request messages to avoid that the server replies 400 Bad Request.

## Cookies

aside

### What cookies can bring:

- authorization
- shopping carts
- recommendations
- user session state (Web e-mail)

### Cookies and privacy:

- cookies permit sites to learn a lot about you
- you may supply name and e-mail to sites

### How to keep "state":

- protocol endpoints: maintain state at sender/receiver over multiple transactions
- cookies: http messages carry state

55

## Web caching

**Goal:** satisfy client request without involving origin server

- user sets browser: Web accesses via cache
- browser sends all HTTP requests to cache
- object in cache: cache returns object
- else cache requests object from origin server, then returns object to client

56

## More about Web caching

57

## More about Web caching

- cache acts as both client and server
- typically cache is installed by the Internet Service Providers (university, company, residential ISP)

### Why Web caching?

- reduce response time for client request
- reduce traffic on an institution's access link.
- Internet dense with caches: enables "poor" content providers to effectively deliver content (but so does P2P file sharing)

58

## Caching Example

### Assumptions

- average object size = 1,000,000 bits
- avg. request rate from institution's browsers to origin servers = 15/sec
- delay from institutional router to any origin server and back to router (Internet delay) = 2 sec

### Consequences

- utilization on LAN = 15%
- utilization on access link = 100%
- total delay = Internet delay + access delay + LAN delay  
= 2 sec + minutes + milliseconds

59

## Caching Example

### Some Computation

$$\text{Lan Traffic Intensity} \\ (15 \text{ requests/sec}) * (1\text{Mb/request})/100\text{Mbps} = 0.15$$

An intensity of 0.15 results in, at most, tens of milliseconds of delay

### Access Link Intensity

$$(15 \text{ requests/sec}) * (1\text{Mb/request})/15\text{Mbps} = 1$$

An intensity of 1 results in a very large delay of the order of minutes

60

## Caching Example (continued)

### possible solution

- increase bandwidth of access link to, say, 100 Mbps

### consequence

- utilization on LAN = 15%
- utilization on access link = 15%
- Total delay = Internet delay + access delay + LAN delay  
= 2 sec + msec + msec
- often a costly upgrade

61

## Caching Example (continued)

### possible solution: install cache

- suppose hit rate is 0.4
- consequence**
  - 40% requests will be satisfied almost immediately (order of milliseconds)
  - 60% requests satisfied by origin server
  - utilization of access link reduced to 60%, resulting in negligible delays (say 10 msec)
  - total avg delay = Internet delay + access delay + LAN delay =  $6 * (2.01)$  secs +  $.4 * \text{milliseconds} < 1.4$  secs

62

## Problem

- Web caches can reside in a client (managed by the user's browser) or in an intermediate network cache server
- Problem: a copy of an object residing in the cache may be *stale* (object housed in the Web server may have been modified since the copy was cached at the client)
- Solution: the conditional GET
  - The request message uses the GET method
  - The request message includes an If-Modified-Since: header line

63

## Conditional Cache

- Goal:** don't send object if cache has up-to-date cached version
- cache: specify date of cached copy in HTTP request  
**If-Modified-Since:** <date>
- server: response contains no object if cached copy is up-to-date:  
**HTTP/1.0 304 Not Modified**

64
